# ATTRIBUTE BASED ACCESS CONTROL

---

Draft

February 21, 2014

[abac-nccoe@nist.gov](mailto:abac-nccoe@nist.gov)

*The National Cybersecurity Center of Excellence (NCCoE) at the National Institute of Standards and Technology addresses businesses’ most pressing cybersecurity problems with practical, standards-based solutions using commercially available technologies. The NCCoE collaborates with industry, academic and government experts to build modular, open, end-to-end reference designs that are broadly applicable and repeatable.*

*This document describes a problem that is relevant to many industry sectors. NCCoE cybersecurity experts will address this challenge through collaboration with a community of interest including vendors of cybersecurity solutions. The solution will become an NCCoE “building block”: an approach that can be incorporated into multiple use cases. The solution proposed by this effort will not be the only one available in the fast-paced cybersecurity technology market. If you would like to propose an alternative architecture or know of products that might be applicable to this challenge, please contact us at [abac-nccoe@nist.gov](mailto:abac-nccoe@nist.gov).*

## 1 1. DESCRIPTION

2 Enterprises have long recognized the need to validate the identity (authentication) of subjects<sup>1</sup>  
3 interacting with their data, systems and networks. Once subjects are identified, strong access  
4 control (authorization) mechanisms are required to ensure that resources are only available to  
5 an authorized subject. To enable a wide array of automated security decisions within and  
6 between enterprises, the identity and access control field has moved from individual access  
7 control lists, to centralized identity stores (databases), to role based access control, and now  
8 attribute based access control (ABAC).

### 9 Goal

10 ABAC enables a rich set of access control policies that allow for fine-grain authentication and  
11 access control decisions based on information about a subject (such as title, division,  
12 certifications and training), rather than pre-provisioned enterprise roles. In conjunction with a  
13 service that enables a range of identity attributes to be accessed or verified, ABAC  
14 implementations enable a federated identity management environment, which makes it  
15 possible to share IT resources across multiple enterprises. When access control decisions can be  
16 this granular, enterprise risks—including insider threats, loss of personally identifiable  
17 information and fraud—are reduced.

18 This building block will use commercially available technologies to demonstrate an enterprise-  
19 class ABAC implementation that enables federated identity management between multiple

---

<sup>1</sup> Typically the *subject* we’re referring to is a user or a device. For consistency with other literature on ABAC, we use the term *subject* throughout this document.

20 enterprises through the use of an attributed exchange service. These technologies enhance the  
21 granularity of access control policies by increasing the range of possible attributes available  
22 when making automated access control decisions in an enterprise. The ABAC technology  
23 solution stack demonstrated in this document is designed to be modular, allowing corporations  
24 flexibility in their implementations based on their current network infrastructures.

## 25 Background

26 The NIST Computer Security Division describes attribute based access control as an evolution  
27 from basic access control lists and more complex role based access. Attribute based access  
28 control “is a highly flexible method for providing access based on the evaluation of attributes.”

29 They continue:

30 “ABAC is a logical access control model that is distinguishable because it controls access  
31 to objects by evaluating rules against the attributes of the entities’ (subject and object)  
32 actions and the environment relevant to a request. ... In its most basic form, ABAC relies  
33 upon the evaluation of attributes of the subject, attributes of the object, environment  
34 conditions, and a formal relationship or access control rule defining the allowable  
35 operations for subject-object attribute and environment condition combinations. All  
36 ABAC solutions contain these basic core capabilities that evaluate attributes and  
37 environment conditions, and enforce rules or relationships between those attributes  
38 and environment conditions.” ...

39 “The rules or policies that can be implemented in an ABAC model are limited only to the  
40 degree imposed by the computational language. This flexibility enables the greatest  
41 breadth of subjects to access the greatest breadth of objects without specifying  
42 individual relationships between each subject and each object.” ...

43 “Provisioning ABAC describes attributes to subjects and objects governed by an access  
44 control rule set that specifies what operations can take place. This capability enables  
45 object owners or administrators to apply access control policy without prior knowledge  
46 of the specific subject and for an unlimited number of subjects that might require  
47 access. As new subjects join the organization, rules and objects do not need to be  
48 modified. As long as the subject is assigned the attributes necessary for access to the  
49 required objects, no modifications to existing rules or object attributes are required.”<sup>2</sup>

## 50 2. SCENARIOS

51 While the security mechanisms employed in this building block could address a wide array of  
52 challenges across various enterprises, this building block will initially focus on a reference  
53 design that demonstrates an ABAC deployment for two first responder scenarios:

### 54 Example Scenario 1 – Dynamic Certificate Provisioning

55 A natural disaster causes a power outage for a major electric power distributor, Utility A. Line  
56 crews are dispatched from unaffected utilities in neighboring regions. Individual members of  
57 the line crews present credentials from their home utility, Utility B. Utilities A and B have both  
58 previously signed an agreement with a third party allowing for the validation of employee  
59 credentials and sharing of attributes.

60 Utility A provides the line crew with a device (such as a laptop or tablet) that connects into its  
61 enterprise network and provides access to the ticketing system and other key information  
62 necessary to repair outages. To log into the device, and into the corporate network of Utility A,  
63 an individual from the line crew presents his Utility B credentials. This could be a subject name  
64 and password, physical token, or biometric. After the subject is authenticated, attributes such  
65 as employee status, certifications, specialties, training and safety record are authorized for  
66 exchange by the lineman and shared by an attribute provider (AP) with Utility A's identity and  
67 access management system (IDAM). Once received, the IDAM system makes decisions about  
68 assignments and access control. Utility A adds a corresponding temporary entry in its  
69 centralized identity management store and provisions a certificate for any device that the line  
70 crew may use in the field, sometimes without network connectivity.

### 71 Example Scenario 2 – Extended Federation

72 A hospital faces a crisis requiring the influx of temporary additional personnel (nurses, doctors,  
73 administrators, etc.). A doctor who works in a different region deploys to assist the hospital. In  
74 similar fashion to the first scenario, both the hospital and the doctor's home practice are  
75 subscribers of a third party service, which allows for the validation of member credentials and  
76 sharing of other attributes. Attributes such as employee status, medical specialization and  
77 certifications are authorized for release by the doctor and shared with the hospital through the  
78 third party service. Because the hospital is operating in an "always on" network-connected  
79 environment, an account is not created. When the doctor presents her home credentials to any  
80 hospital device or service, the service queries the third party network to authenticate her  
81 credentials and authorize access for that session.

## 82 3. SECURITY CHARACTERISTICS

83 To address these two scenarios, this project will use commercially available technology to  
84 demonstrate characteristics that are considered attributes of a secure solution. Each  
85 characteristic has one or more examples of security capabilities that can meet the intent of the

86 characteristic. The below list of characteristics and corresponding capabilities is not exhaustive.  
 87 Furthermore, capabilities are defined to provide context for the characteristics and are not  
 88 meant to be prescriptive. In implementing these characteristics, the build will focus on use of  
 89 technologies that provide the greatest level of configurability and flexibility in achieving the  
 90 below characteristics.

Security characteristics	Example capabilities
audit and monitoring	<ul style="list-style-type: none"> <li>• logs all access requests, access decisions, attributes used and subject identities</li> <li>• provides canned reports, queries and analysis</li> </ul>
data protection	<ul style="list-style-type: none"> <li>• encrypts the transmission of attributes traveling between enterprises and across the attribute exchange service</li> <li>• encrypts data for all attribute and policy stores</li> <li>• protects attribute values used within policy decision logic</li> </ul>
attribute integrity verification	<ul style="list-style-type: none"> <li>• provides the relying party (RP) with assurance that the attributes received are from the intended source and have not been modified</li> <li>• supports strong authentication between the RP and attribute provider (AP)</li> </ul>
policy enforcement	<ul style="list-style-type: none"> <li>• ensures appropriate action is taken for failed authentication and authorization</li> <li>• reduces (or eliminates) false positive/false negative results</li> </ul>
identity lifecycle management	<ul style="list-style-type: none"> <li>• provisions and de-provisions accounts</li> <li>• manages:               <ul style="list-style-type: none"> <li>○ subject attribute</li> <li>○ object attribute</li> <li>○ environment attribute</li> <li>○ federated identity and attribute</li> <li>○ policy, e.g., certificate expiration</li> </ul> </li> </ul>
attribute validation	<ul style="list-style-type: none"> <li>• periodically revalidates each attribute in use</li> </ul>
privacy protection	<ul style="list-style-type: none"> <li>• identity providers should not know the relying party in any given transaction</li> <li>• prevents the attribute exchange service from tracking subject across multiple transactions</li> <li>• eavesdroppers cannot decode messages or determine that two authentication sessions involved the same subject</li> </ul>
multi-factor authentication	<ul style="list-style-type: none"> <li>• support requirements for multi-factor authentication to achieve degrees of authentication confidence using a combination of factors such as physical and logical tokens and biometric factors</li> </ul>

## 91 4. APPROACH

92 This building block focuses on the demonstration of ABAC technologies and how they can be  
93 integrated to address challenges across a wide-array of business sectors. The initial focus is on  
94 the creation and demonstration of a service that supports identity and attribute verification  
95 and exchange between attribute providers, identity providers and relying parties.

96 It should be noted that this is an initial approach and that the building block process is intended  
97 to be iterative. As technologies and capabilities evolve, the initial technology stack of this  
98 building block may be augmented with additional functions.

### 99 Stage 0 – Creation and Demonstration of an Attribute Exchange Service

- 100 • set up RP, AP and identity provider (IdP)
- 101 • set up a server with a commercially available or open source operating system
- 102 • install a target identity management software for authentication and authorization that  
103 includes a database to serve as an identity store (RP)
- 104 • connect the identity management software to one or more target applications that  
105 require authentication and access control
- 106 • set up a server running a corporate identity store to serve as a repository for identity  
107 and attribute information and that has exposed application programming interfaces for  
108 federated connections (IdP, AP)
- 109 • connect the RP server to an attribute exchange (AE) service
- 110 • connect the IdP and AP server to the AE service

### 111 Stage 1 – Test RP Subject Authentication Based on Attribute Assertions

- 112 • set policy in the RP or AE for acceptable sources of identity information
- 113 • create a test account in the IdP
- 114 • ensure that the RP can validate a subject by connecting through the attribute exchange  
115 service to authenticate using subject name and password
- 116 • test dynamic certificate provisioning

### 117 Stage 2 – Test Authorization of RP Resources Based on Attribute Assertions from an AP

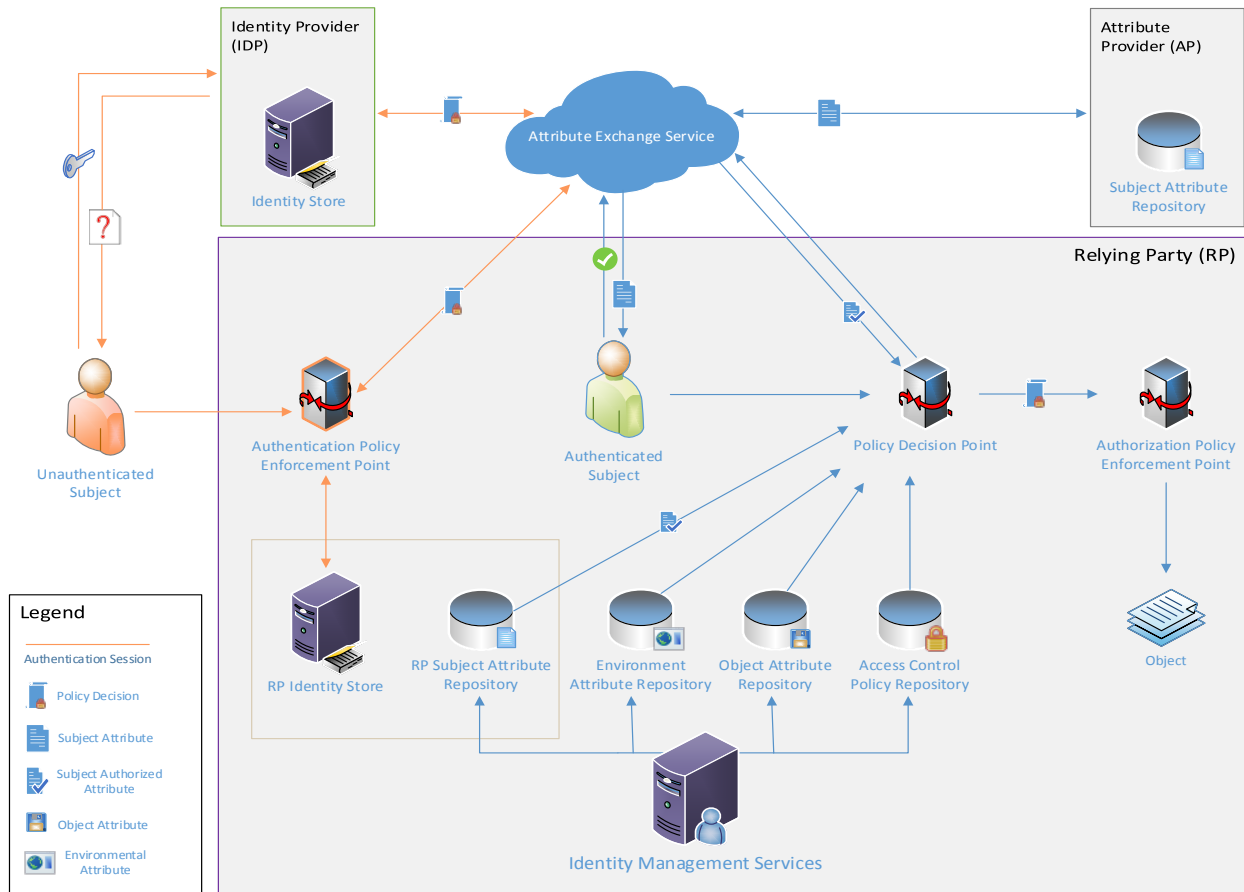

- 118 • validate policy decision and policy enforcement logic
- 119 • create and test multiple environmental contexts
- 120 • stand up audit server and log analysis engine

### 121 Stage 3 – Add Multifactor Authentication Components to RP Authentication of Subjects

- 122 • implement tiered multifactor authentication based on risk analysis (including data  
123 sensitivity, environmental attributes, user attributes, etc.)

137 **6. HIGH-LEVEL ARCHITECTURE**

138

139 **7. COMPONENT LIST**

- 140 • commercially available operating system
- 141 • identity management software that includes functions like: account provisioning, de-
- 142 provisioning, multi-factor authentication, group assignment, role assignment, user self
- 143 service and federation
- 144 • attribute exchange service
- 145 • commercially available database (policy database, identity store, subject attribute
- 146 repository, object attribute repository)
- 147 • access control mechanism (policy decision point, policy enforcement point, context
- 148 handler)
- 149 • cryptographic means to protect subject privacy during interactions between RPs, IDPs,
- 150 APs, and the attribute exchange service. Privacy mechanisms must protect subject
- 151 behavior from being tracked (i.e. which RPs the subject interacts with) and protect the
- 152 confidentiality of subject attributes
- 153 • standard method for the exchange of authentication and authorization data between
- 154 parties
