# DATA INTEGRITY

## Reducing the impact of an attack

DRAFT  
November 23, 2015  
[di-nccoe@nist.gov](mailto:di-nccoe@nist.gov)

The National Cybersecurity Center of Excellence (NCCoE) at the National Institute of Standards and Technology (NIST) works with industry, academic, and government experts to find practical solutions for businesses' most pressing cybersecurity needs. The NCCoE demonstrates how standards and best practices established by NIST and other organizations can be applied in technical reference architectures and serves as a collaboration hub where small businesses, market-leading companies, government agencies, and individuals from academia work together to address broad cybersecurity problems. To learn more about the NCCoE, visit <https://nccoe.nist.gov>. To learn more about NIST, visit <http://www.nist.gov>.

NCCoE building blocks address technology gaps that affect multiple industry sectors. They represent core capabilities that can and should be applied across industry cybersecurity and business use cases.

## ABSTRACT

Constant threats of destructive malware, malicious insider activity, and even honest mistakes create the imperative for organizations to be able to quickly recover from an event that alters or destroys any form of data (database records, system files, configurations, user files, application code, etc.). Further, businesses must be confident that recovered data is accurate and safe. The National Cybersecurity Center of Excellence (NCCoE)—in collaboration with members of the business community and vendors of cybersecurity solutions—is creating an example solution to address these complex data integrity challenges.

Multiple systems need to work together to prevent, detect, notify, and recover when data integrity is jeopardized. This project explores methods to effectively monitor and detect data corruption in commodity components (server, operating system, applications, and software configurations) as well as custom applications and data. It also explores issues of auditing and reporting (user activity monitoring, file system monitoring, database monitoring, scanning backups/snapshots for malware and rapid recovery solutions) to support recovery and investigations. To address real-world business challenges around data integrity, the resulting example solution will be composed of open-source and commercially available components. Ultimately, this project will result in a publicly available NIST Cybersecurity Practice Guide—a description of the solution and practical steps needed to implement an example solution that addresses these existing challenges.

## KEYWORDS

*business continuity, malware, ransomware, integrity, attack vector, data recovery, malicious actor*

## DISCLAIMER

Certain commercial entities, equipment, or materials may be identified in this document in order to describe an experimental procedure or concept adequately. Such identification is not intended to imply recommendation or endorsement by NIST or NCCoE, nor is it intended to imply that the entities, materials or equipment are necessarily the best available for the purpose.

## COMMENTS ON NCCoE DOCUMENTS

Organizations are encouraged to review all draft publications during public comment periods and provide feedback. All publications from NIST's National Cybersecurity Center of Excellence are available at <http://nccoe.nist.gov>.

Comments on this publication may be submitted to: [DI-NCCoE@nist.gov](mailto:DI-NCCoE@nist.gov)

Public comment period: *November 23, 2015 to January 22, 2016*

## 1 1. EXECUTIVE SUMMARY

2 The NCCoE is responding to industries that have identified the problem of data  
3 corruption by malicious actors. In order to remain operational, an organization should  
4 be able to quickly recover from a data integrity attack and trust that the recovered data  
5 is accurate, complete, and free of malware.

6 Malicious actors are intent on disrupting operations or achieving financial gain and will  
7 corrupt critical information maintained by an organization to achieve their goals.  
8 Information such as customer data, transaction records, and correspondence are  
9 typically the targets for unauthorized insertion, modification or deletion. These types of  
10 data integrity attacks, especially when they target an entire organization, can lead to  
11 catastrophic impacts and impair the company's ability to operate. There is evidence of  
12 malicious actors attempting and successfully corrupting high-value data across various  
13 industries. In other cases, systems are held hostage by a specific type of malware called  
14 ransomware, which encrypts various types of data files on a system so the users can no  
15 longer use them, and then demands a payment for the decryption keys for the files.

16 There are many attack vectors that a data integrity attack can utilize to gain access to  
17 corporate systems. Typical attack vectors include phishing (email), drive-by website  
18 downloads, unmitigated vulnerabilities on externally facing resources, and  
19 malicious/infected attachments. Once the malware is operational it can use multiple  
20 techniques to spread throughout an organization, exfiltrate data, and corrupt it. The  
21 data at risk includes but is not limited to: active, current data, back-up data, system  
22 configurations, and baseline system operating systems.

23 The project described in this document will help organizations address the issue of  
24 detecting and recovering from a data integrity attack on its data. The data includes  
25 databases, stored files, configurations, operating system files, as well as other types of  
26 files. These types of files can be corrupted before or after they have been stored to a  
27 back-up system. One example is undetected malware that is stored in system back-ups  
28 prior to detection.

29 The project will include an architectural depiction and example solution that can reduce  
30 the risk and impact of a data integrity attack. The solution will integrate commercial  
31 and open source products. The project will result in a NIST Cybersecurity Practice  
32 Guide. The practice guide provides a description of the practical steps needed to  
33 implement the proposed architecture. Organizations will be able to use the practice  
34 guide to influence architectural changes that enhance their ability to recover from data  
35 corruption attacks.

## 36 2. BUSINESS VALUE

37 Corporate resilience against data corruption is critical to business continuity, cost  
38 avoidance and regulatory compliance. The potential business benefits of the data  
39 integrity solution explored by this project include:

- 40 • Detecting back-up data tampering attempts
- 41 • Reducing the impact of a data corruption attack
- 42 • Reducing downtime caused by data corruption
- 43 • Improving IT resource efficiency through automated testing
- 44 • Improving trustworthiness of back-up data
- 45 • Reducing the negative impact to the reputation of an organization due to data  
46 corruption events
- 47 • Providing management with overall health and status of the organization's data  
48 and continuity of operations

## 49 3. DESCRIPTION

### 50 Who should read this document?

51 The intended audience for this document is CIO, CISO and IT management personnel  
52 interested in mitigating the threat of data corruption caused by malicious actors as well  
53 as unintentional human or computer error.

### 54 Goal

55 The goal of this project is to help prevent the use of corrupted data when recovering  
56 systems from back-up storage. The solution will provide guidance for incorporating data  
57 corruption prevention, detection, and recovery into a corporate IT architecture. In  
58 addition to protecting critical enterprise information, corruption alerts and activity logs  
59 provide the security analysts with indicators of malicious activity. The project will explore  
60 methods to monitor and protect commodity components (operating systems,  
61 applications, and software configurations), custom applications, and data (database and  
62 files). It will produce an architecture that includes components that will integrate  
63 detection and notification of data corruption events as well as approaches to  
64 automation for recovery from such events.

65 The project will also include auditing and reporting (user activity monitoring, file system  
66 monitoring, database monitoring, scanning backups/snapshots for corruption or  
67 malware) to support investigations.

### 68 Background

69 The NCCoE, working with the organizations across the set of critical infrastructure  
70 industries, including information sharing and analysis centers (ISACs) identified the need

71 for a data integrity solution. The center held a workshop to identify key issues that  
72 affect consumer data protection, encapsulated in NISTIR 8050. This document  
73 identified data integrity (among other items) as a key cybersecurity issue that needs to  
74 be addressed. The need arises from the recognition that malicious actors are devising  
75 methods of corrupting data within organizations. The data corruption includes data  
76 modification as well as data destruction. In addition the center met with  
77 representatives the financial sector ISAC (FS-ISAC) for guidance, and has been working  
78 with the FS-ISAC Destructive Malware Data Integrity Task Force.

## 79 **Scope**

80 This project will answer specific questions pertaining to data integrity and recovery such  
81 as:

- 82 • What data was corrupted? When was it corrupted? How it was corrupted? Who  
83 corrupted it?
- 84 • Do any other events coincide with this corruption?
- 85 • What was the impact of the data corruption? (Systems affected, timelines, etc.)
- 86 • Which backup version should be used to recover data?

87

88 This project will address three solution areas:

- 89 1) File system integrity solution to allow recovery from trusted backups and  
90 snapshots.
- 91 2) Database integrity solution with transactions and versioning to allow for  
92 rollbacks to a known good state.
- 93 3) An overall automated system that incorporates the previous two areas and  
94 includes the following:
  - 95 a. Activity logging and monitoring.
  - 96 b. Versioning and journaling file system solutions that incorporate formal  
97 change management procedures covering both normal and emergency  
98 changes to systems.
  - 99 c. Restoration of desktops, applications, and critical services quickly after  
100 cyber incidents.
  - 101 d. Alert systems to notify administrators when baseline controls are  
102 changed on critical systems.

103

## 104 **Assumptions**

105 This project assumes data integrity needs to be addressed for each of the following  
106 components:

- 107 • Operating Systems

- 108 • File System
- 109 • Applications (including custom code)
- 110 • Databases
- 111 • Virtual machines (including software defined networks)

## 112 4. EXAMPLE SCENARIOS

113 The example scenarios below illustrate some of the challenges that this project will  
114 address. The relevant functions and categories from the NIST Framework for Improving  
115 Critical Infrastructure Cybersecurity (CSF) that can be employed to mitigate the events  
116 throughout the attack are listed below.

### 117 Scenario 1 - Ransomware

118 For financial gain, an organized crime group has set up multiple seemingly legitimate  
119 domains that contain destructive malware to be automatically downloaded and  
120 discreetly/silently installed, without the user's knowledge, when a website on the  
121 domain is visited. Once the malware is installed it can encrypt the organization's file  
122 system and require a ransom payment in order to unencrypt the files to be restored.  
123 Left unmitigated, the malware on one system is designed to move laterally within the  
124 network to other client and server systems within an organization's network, encrypting  
125 those systems and demanding ransom before access to those systems can be restored.

126 The project addresses respond and recover CSF categories

- 127 • Malware encrypts files and displays notice demanding payment for decryption
  - 128 ○ Respond/Recover:
    - 129 ▪ notify security (DE.DP-4, RS.CO-2, DE.EA-5)
    - 130 ▪ file integrity monitor (PR.DS-1, PR.DS-6, PR.PT-1)

131 The project does not address these protect and detect CSF categories

- 132 • User receives phishing email with executable attachment
  - 133 ○ Protect/Detect: email security and attachment scanning
- 134 • User runs the attachment containing malware which installs and infects the  
135 user's machine
  - 136 ○ Protect/Detect: Host-based Anti-malware, application whitelisting, EMET,  
137 sandboxing/virtualization
- 138 • Malware sets up command and control where it receives instructions and  
139 cryptographic keys
  - 140 ○ Protect/Detect: Host-based firewall/IDS, network-based firewall/IDS
  - 141

142

143 **Scenario 2 - Data destruction**

144 An adversary wishing to impact the operations of a major lending or banking institution  
145 launches a spear-phishing campaign against individuals in the target corporation. Once  
146 any of the human targets clicks on a link or attachment, the malware downloads and  
147 installs itself on that user’s machine, and immediately starts looking to infect other  
148 systems across the enterprise. At a predetermined time, the malware starts encrypting  
149 all data on the infected machines. Then it writes over the original unencrypted content  
150 and deletes the encryption keys.

- 151 The project addresses respond and recover CSF categories
- 152 • Malware destroys data on user’s machine
    - 153 ○ Respond/Recover:
      - 154 ▪ back-ups(PR.DS-1, PR.IP-4)
      - 155 ▪ file integrity monitor (PR.DS-1, PR.DS-6, PR.PT-1)

- 157 The project does not address these protect and detect CSF categories
- 158 • User receives phishing email with executable attachment
    - 159 ○ Protect/Detect: email security and attachment scanning
  - 160 • User runs the attachment containing malware which installs and infects the  
161 user’s machine
    - 162 ○ Protect/Detect: Host-based Anti-malware, application whitelisting, EMET,  
163 sandboxing/virtualization
  - 164 • Malware performs reconnaissance and attempts to spread throughout the  
165 enterprise.
    - 166 ○ Protect/Detect: network-based firewall/IDS, use of P-VLANs

167

168 **Scenario 3 - Data Manipulation (insider threat)**

169 A disgruntled employee seeks to harm his employer by damaging its business  
170 operations, brand, or reputation, and launches a campaign to modify company records.  
171 Using authorized credentials he has, or acquires, he modifies database entries over  
172 time. Because the modifications he makes appear to be legitimate, a significant amount  
173 of data is corrupted before he is discovered.

174

175  
176  
177  
178  
179  
180  
181  
182  
183  
184  
185  
186  
187

- The project address respond and recover CSF categories
- User modifies a configuration file in violation of established baselines
    - Protect/Detect:
      - **file integrity monitor** (PR.DS-1, PR.DS-6, PR.PT-1)
      - **user activity auditing** (DE.CM-3, PR.PT-1)
  - Administrator modifies a user's file
    - Protect/Detect:
      - **file integrity monitor** (PR.DS-1, PR.DS-6, PR.PT-1)
      - **user activity auditing** (DE.CM-3, PR.PT-1, DE.AE-1)
  - Administrator and/or script modifies data in a database
    - Protect/Detect:
      - **database transaction auditing** (PR.DS-1, PR.PT-1, DE.CM-1)

188

## 5. CURRENT CHALLENGES

189

### Detecting Data Corruption in Back-ups

190  
191  
192  
193

Data back-up software and systems focus on accurately restoring data as originally stored. This approach is effective for data that is known to be 100% error free and uncorrupted. These systems generally do not provide a retroactive data testing scheme to test data for corruption by insiders or malicious applications while in storage.

194

### Detecting malware in back-up data

195  
196  
197  
198  
199  
200  
201  
202  
203

Data back-up software and systems generally do not have manual or automated testing capabilities to identify and remediate malware in backed up data. Malware detection is typically done at runtime in operational systems by anti-virus/anti-malware software. In addition the software is not designed to test data in non-realtime. Malware that is designed to be dormant for periods of time may not be detectable until active with current anti-virus/anti-malware software. A time-shifting, self-contained testing environment that can emulate the passage of time may be able to detect time-sensitive or time-delayed malware activity in addition to malware with signatures for activity monitoring that was unknown at the time the backup was completed.

204

### Automation of Backup Data Testing

205  
206  
207

Back-up data testing is typically used to verify that back-up data can be used to restore systems to operational readiness. Data back-up software and systems generally do not offer automated backup data integrity or malware testing capabilities.

208

## 245 **7. DESIRED SOLUTION CHARACTERISTICS**

246 To address the three scenarios, this project will use a collection of commercially  
247 available technologies to demonstrate security and functional characteristics of a data  
248 integrity solution. The data integrity solution shall include the following characteristics:

- 249 • Automated data corruption testing
- 250 • Automated data corruption detection
- 251 • Automated data corruption event logging
- 252 • Secure data integrity monitoring and alerting information (checksums,  
253 off-site, hard-copy)
- 254 • Automated detection and reporting of all file modifications / creations /  
255 deletions
- 256 • Automated detection and reporting of all database modifications /  
257 creations / deletions
- 258 • Automated correlation of file changes and users
- 259 • Automated user activity recording
- 260 • Automated anomalous user activity detection
- 261 • Automated configuration management monitoring

## 262 **8. SECURITY CONTROL MAP**

263 Table 1 maps the characteristics of the applicable standards and best practices  
264 described in the Framework for Improving Critical Infrastructure Cybersecurity (CSF),  
265 and other NIST activities. This exercise is meant to demonstrate the real-world  
266 applicability of standards and best practices, but does not imply that these  
267 characteristics will meet your industry's requirements.

 273 prescriptive.

274

275 **9. HIGH-LEVEL ARCHITECTURE**

276 The figure below depicts the proposed high-level environment and architecture to help  
 277 ensure data integrity within the enterprise.

Figure 1. Data Integrity Building Block high-level architecture

281

282 **10.COMPONENT LIST**

283 Data integrity solutions include but are not limited to the following components:

- 284 • File integrity monitors
- 285 • File versioning
- 286 • File integrity testing
- 287 • User activity monitoring
- 288 • Configuration management
- 289 • Database rollbacks
- 290 • Virtual machine integrity/snapshots/versioning
- 291 • Versioning file systems
- 292 • Journaling file systems

293 Some of these are subcomponents of the components shown in the architecture in  
294 section 9.
