1 **DISCLAIMER**

2 Certain commercial entities, equipment, products, or materials may be identified by name or company  
3 logo or other insignia in order to acknowledge their participation in this collaboration or to describe an  
4 experimental procedure or concept adequately. Such identification is not intended to imply special  
5 status or relationship with NIST or recommendation or endorsement by NIST or NCCoE; neither is it  
6 intended to imply that the entities, equipment, products, or materials are necessarily the best available  
7 for the purpose.

8 National Institute of Standards and Technology Special Publication 1800-36B, Natl. Inst. Stand. Technol.  
9 Spec. Publ. 1800-36B, 114 pages, May 2024, CODEN: NSPUE2

10 **FEEDBACK**

11 You can improve this guide by contributing feedback regarding which aspects of it you find helpful as  
12 well as suggestions on how it might be improved. Should we provide guidance summaries that target  
13 specific audiences? What trusted IoT device onboarding protocols and related features are most  
14 important to you? Is there some content that is not included in this document that we should cover? Are  
15 we missing anything in terms of technologies or use cases? In what areas would it be most helpful for us  
16 to focus our future related efforts? For example, should we consider implementing builds that onboard  
17 devices supporting Matter and/or the Fast Identity Online (FIDO) Alliance application onboarding  
18 protocol? Should we implement builds that integrate security mechanisms such as lifecycle  
19 management, supply chain management, attestation, or behavioral analysis? As you review and adopt  
20 this solution for your own organization, we ask you and your colleagues to share your experience and  
21 advice with us.

## 31 NATIONAL CYBERSECURITY CENTER OF EXCELLENCE

32 The National Cybersecurity Center of Excellence (NCCoE), a part of the National Institute of Standards  
 33 and Technology (NIST), is a collaborative hub where industry organizations, government agencies, and  
 34 academic institutions work together to address businesses' most pressing cybersecurity issues. This  
 35 public-private partnership enables the creation of practical cybersecurity solutions for specific  
 36 industries, as well as for broad, cross-sector technology challenges. Through consortia under  
 37 Cooperative Research and Development Agreements (CRADAs), including technology partners—from  
 38 Fortune 50 market leaders to smaller companies specializing in information technology security—the  
 39 NCCoE applies standards and best practices to develop modular, adaptable example cybersecurity  
 40 solutions using commercially available technology. The NCCoE documents these example solutions in  
 41 the NIST Special Publication 1800 series, which maps capabilities to the NIST Cybersecurity Framework  
 42 and details the steps needed for another entity to re-create the example solution. The NCCoE was  
 43 established in 2012 by NIST in partnership with the State of Maryland and Montgomery County,  
 44 Maryland.

45 To learn more about the NCCoE, visit <https://www.nccoe.nist.gov/>. To learn more about NIST, visit  
 46 <https://www.nist.gov/>.

## 47 NIST CYBERSECURITY PRACTICE GUIDES

48 NIST Cybersecurity Practice Guides (Special Publication 1800 series) target specific cybersecurity  
 49 challenges in the public and private sectors. They are practical, user-friendly guides that facilitate the  
 50 adoption of standards-based approaches to cybersecurity. They show members of the information  
 51 security community how to implement example solutions that help them align with relevant standards  
 52 and best practices, and provide users with the materials lists, configuration files, and other information  
 53 they need to implement a similar approach.

54 The documents in this series describe example implementations of cybersecurity practices that  
 55 businesses and other organizations may voluntarily adopt. These documents do not describe regulations  
 56 or mandatory practices, nor do they carry statutory authority.

## 57 KEYWORDS

58 *application-layer onboarding; bootstrapping; Internet of Things (IoT); Manufacturer Usage Description*  
 59 *(MUD); network-layer onboarding; onboarding; Wi-Fi Easy Connect.*

## 60 ACKNOWLEDGMENTS

61 We are grateful to the following individuals for their generous contributions of expertise and time.

Name	Organization
Amogh Guruprasad Deshmukh	Aruba, a Hewlett Packard Enterprise company
Bart Brinkman	Cisco

Name	Organization
Eliot Lear	Cisco
George Grey	Foundries.io
David Griego	Foundries.io
Fabien Gremaud	Kudelski IoT
Faith Ryan	The MITRE Corporation
Toby Ealden	NquiringMinds
John Manslow	NquiringMinds
Antony McCaigue	NquiringMinds
Alexandru Mereacre	NquiringMinds
Loic Cavaille	NXP Semiconductors
Mihai Chelalau	NXP Semiconductors
Julien Delplancke	NXP Semiconductors
Anda-Alexandra Dorneanu	NXP Semiconductors
Todd Nuzum	NXP Semiconductors
Nicusor Penisoara	NXP Semiconductors
Laurentiu Tudor	NXP Semiconductors
Karen Scarfone	Scarfone Cybersecurity
Pedro Fuentes	SEALSQ, a subsidiary of WISEKey
Gweltas Radenac	SEALSQ, a subsidiary of WISEKey
Kalvin Yang	SEALSQ, a subsidiary of WISEKey

62 The Technology Partners/Collaborators who participated in this build submitted their capabilities in  
63 response to a notice in the Federal Register. Respondents with relevant capabilities or product  
64 components were invited to sign a Cooperative Research and Development Agreement (CRADA) with  
65 NIST, allowing them to participate in a consortium to build this example solution. We worked with:

## 71 DOCUMENT CONVENTIONS

72 The terms “shall” and “shall not” indicate requirements to be followed strictly to conform to the  
73 publication and from which no deviation is permitted. The terms “should” and “should not” indicate that  
74 among several possibilities, one is recommended as particularly suitable without mentioning or  
75 excluding others, or that a certain course of action is preferred but not necessarily required, or that (in  
76 the negative form) a certain possibility or course of action is discouraged but not prohibited. The terms  
77 “may” and “need not” indicate a course of action permissible within the limits of the publication. The  
78 terms “can” and “cannot” indicate a possibility and capability, whether material, physical, or causal.

79 **CALL FOR PATENT CLAIMS**

80 This public review includes a call for information on essential patent claims (claims whose use would be  
81 required for compliance with the guidance or requirements in this Information Technology Laboratory  
82 (ITL) draft publication). Such guidance and/or requirements may be directly stated in this ITL Publication  
83 or by reference to another publication. This call also includes disclosure, where known, of the existence  
84 of pending U.S. or foreign patent applications relating to this ITL draft publication and of any relevant  
85 unexpired U.S. or foreign patents.

86 ITL may require from the patent holder, or a party authorized to make assurances on its behalf, in  
87 written or electronic form, either:

88 a) assurance in the form of a general disclaimer to the effect that such party does not hold and does not  
89 currently intend holding any essential patent claim(s); or

90 b) assurance that a license to such essential patent claim(s) will be made available to applicants desiring  
91 to utilize the license for the purpose of complying with the guidance or requirements in this ITL draft  
92 publication either:

- 93 1. under reasonable terms and conditions that are demonstrably free of any unfair discrimination; or  
94 2. without compensation and under reasonable terms and conditions that are demonstrably free of  
95 any unfair discrimination.

96 Such assurance shall indicate that the patent holder (or third party authorized to make assurances on its  
97 behalf) will include in any documents transferring ownership of patents subject to the assurance,  
98 provisions sufficient to ensure that the commitments in the assurance are binding on the transferee,  
99 and that the transferee will similarly include appropriate provisions in the event of future transfers with  
100 the goal of binding each successor-in-interest.

101 The assurance shall also indicate that it is intended to be binding on successors-in-interest regardless of  
102 whether such provisions are included in the relevant transfer documents.

103 Such statements should be addressed to: [iot-onboarding@nist.gov](mailto:iot-onboarding@nist.gov).

## 251 1 Summary

252 IoT devices are typically connected to a network. As with any other device needing to communicate on a  
253 network securely, an IoT device needs credentials that are specific to that network to help ensure that  
254 only authorized devices can connect to and use the network. A typical commercially available, mass-  
255 produced IoT device cannot be pre-provisioned with local network credentials by the manufacturer  
256 during the manufacturing process. Instead, the local network credentials will be provisioned to the  
257 device at the time of its deployment. This practice guide is focused on trusted methods of providing IoT  
258 devices with the network-layer credentials and policy they need to join a network upon deployment, a  
259 process known as *network-layer onboarding*.

260 Establishing trust between a network and an IoT device (as defined in [NIST Internal Report 8425](#)) prior to  
261 providing the device with the credentials it needs to join the network is crucial for mitigating the risk of  
262 potential attacks. There are two possibilities for attack. One is where a device is convinced to join an  
263 unauthorized network, which would take control of the device. The other is where a network is  
264 infiltrated by a malicious device. Trust is achieved by attesting and verifying the identity and posture of  
265 the device and the network before providing the device with its network credentials—a process known  
266 as *network-layer onboarding*. In addition, scalable, automated mechanisms are needed to safely manage  
267 IoT devices throughout their lifecycles, such as safeguards that verify the security posture of a device  
268 before the device is permitted to execute certain operations.

269 In this practice guide, the National Cybersecurity Center of Excellence (NCCoE) applies standards, best  
270 practices, and commercially available technology to demonstrate various mechanisms for trusted  
271 network-layer onboarding of IoT devices. This guide shows how to provide network credentials to IoT  
272 devices in a trusted manner and maintain a secure device posture throughout the device lifecycle.

### 273 1.1 Challenge

274 With 40 billion IoT devices expected to be connected worldwide by 2025 [\[1\]](#), it is unrealistic to onboard  
275 or manage these devices by visiting each device and performing a manual action. While it is possible for  
276 devices to be securely provided with their local network credentials at the time of manufacture, this  
277 requires the manufacturer to customize network-layer onboarding on a build-to-order basis, which  
278 prevents the manufacturer from taking full advantage of the economies of scale that could result from  
279 building identical devices for all its customers.

280 The industry lacks scalable, automatic mechanisms to safely manage IoT devices throughout their  
281 lifecycles and lacks a trusted mechanism for providing IoT devices with their network credentials and  
282 policy at the time of deployment on the network. It is easy for a network to falsely identify itself, yet  
283 many IoT devices onboard to networks without verifying the network's identity and ensuring that it is  
284 their intended target network. Also, many IoT devices lack user interfaces, making it cumbersome to  
285 manually input network credentials. Wi-Fi is sometimes used to provide credentials over an open (i.e.,  
286 unencrypted) network, but this onboarding method risks credential disclosure. Most home networks use  
287 a single password shared among all devices, so access is controlled only by the device's possession of  
288 the password and does not consider a unique device identity or whether the device belongs on the  
289 network. This method also increases the risk of exposing credentials to unauthorized parties. Providing

290 unique credentials to each device is more secure, but doing so manually would be resource-intensive  
291 and error-prone, would risk credential disclosure, and cannot be performed at scale.

292 Once a device is connected to the network, if it becomes compromised, it can pose a security risk to  
293 both the network and other connected devices. Not keeping such a device current with the most recent  
294 software and firmware updates may make it more susceptible to compromise. The device could also be  
295 attacked through the receipt of malicious payloads. Once compromised, it may be used to attack other  
296 devices on the network.

## 297 1.2 Solution

298 We need scalable, automated, trusted mechanisms to safely manage IoT devices throughout their  
299 lifecycles to ensure that they remain secure, starting with secure ways to provision devices with their  
300 network credentials, i.e., beginning with network-layer onboarding. Onboarding is a particularly  
301 vulnerable point in the device lifecycle because if it is not performed in a secure manner, then both the  
302 device and the network are at risk. Networks are at risk of having unauthorized devices connect to them,  
303 and devices are at risk of being taken over by networks that are not authorized to onboard or control  
304 them.

305 The NCCoE has adopted the trusted network-layer onboarding approach to promote automated, trusted  
306 ways to provide IoT devices with unique network credentials and manage devices throughout their  
307 lifecycles to ensure that they remain secure. The NCCoE is collaborating with CRADA consortium  
308 technology providers in a phased approach to develop example implementations of trusted network-  
309 layer onboarding solutions. We define a *trusted network-layer onboarding solution* to be a mechanism  
310 for provisioning network credentials to a device that:

- 311     ▪ provides each device with unique network credentials,
- 312     ▪ enables the device and the network to mutually authenticate,
- 313     ▪ sends devices their network credentials over an encrypted channel,
- 314     ▪ does not provide any person with access to the network credentials, and
- 315     ▪ can be performed repeatedly throughout the device lifecycle to enable:
  - 316         • the device's network credentials to be securely managed and replaced as needed, and
  - 317         • the device to be securely onboarded to other networks after being repurposed or resold.

318 The use cases designed to be demonstrated by this project's implementations include:

- 319     ▪ trusted network-layer onboarding of IoT devices
- 320     ▪ repeated trusted network-layer onboarding of devices to the same or a different network
- 321     ▪ automatic establishment of an encrypted connection between an IoT device and a trusted  
322         application service (i.e., *trusted application-layer onboarding*) after the IoT device has  
323         performed trusted network-layer onboarding and used its credentials to connect to the network
- 324     ▪ policy-based ongoing device authorization
- 325     ▪ software-based methods to provision device birth credentials in the factory

- 326       ▪ mechanisms for IoT device manufacturers to provide IoT device purchasers with information  
327       needed to onboard the IoT devices to their networks (i.e., *device bootstrapping information*)

### 328 **1.3 Benefits**

329 This practice guide can benefit both IoT device users and IoT device manufacturers. The guide can help  
330 IoT device users understand how to onboard IoT devices to their networks in a trusted manner to:

- 331       ▪ Ensure that their network is not put at risk as IoT devices are added to it  
332       ▪ Safeguard their IoT devices from being taken over by unauthorized networks  
333       ▪ Provide IoT devices with unique credentials for network access  
334       ▪ Provide, renew, and replace device network credentials in a secure manner  
335       ▪ Ensure that IoT devices can automatically and securely perform application-layer onboarding  
336       after performing trusted network-layer onboarding and connecting to a network  
337       ▪ Support ongoing protection of IoT devices throughout their lifecycles

338 This guide can help IoT device manufacturers, as well as manufacturers and vendors of semiconductors,  
339 secure storage components, and network onboarding equipment, understand the desired security  
340 properties for supporting trusted network-layer onboarding and demonstrate mechanisms for:

- 341       ▪ Placing unique credentials into secure storage on IoT devices at time of manufacture (i.e., *device*  
342       *birth credentials*)  
343       ▪ Installing onboarding software onto IoT devices  
344       ▪ Providing IoT device purchasers with information needed to onboard the IoT devices to their  
345       networks (i.e., *device bootstrapping information*)  
346       ▪ Integrating support for network-layer onboarding with additional security capabilities to provide  
347       ongoing protection throughout the device lifecycle

## 348 **2 How to Use This Guide**

349 This NIST Cybersecurity Practice Guide demonstrates a standards-based reference design for  
350 implementing trusted IoT device network-layer onboarding and lifecycle management and describes  
351 various example implementations of this reference design. Each of these implementations, which are  
352 known as *builds*, is standards-based and is designed to help provide assurance that networks are not put  
353 at risk as new IoT devices are added to them and help safeguard IoT devices from connecting to  
354 unauthorized networks. The reference design described in this practice guide is modular and can be  
355 deployed in whole or in part, enabling organizations to incorporate trusted IoT device network-layer  
356 onboarding and lifecycle management into their legacy environments according to goals that they have  
357 prioritized based on risk, cost, and resources.

358 NIST is adopting an agile process to publish this content. Each volume is being made available as soon as  
359 possible rather than delaying release until all volumes are completed.

360 This guide contains five volumes:

- 361       ▪ NIST Special Publication (SP) 1800-36A: *Executive Summary* – why we wrote this guide, the  
362 challenge we address, why it could be important to your organization, and our approach to  
363 solving this challenge
- 364       ▪ NIST SP 1800-36B: *Approach, Architecture, and Security Characteristics* – what we built and why  
365 **(you are here)**
- 366       ▪ NIST SP 1800-36C: *How-To Guides* – instructions for building the example implementations,  
367 including all the security-relevant details that would allow you to replicate all or parts of this  
368 project
- 369       ▪ NIST SP 1800-36D: *Functional Demonstrations* – use cases that have been defined to showcase  
370 trusted IoT device network-layer onboarding and lifecycle management security capabilities,  
371 and the results of demonstrating these use cases with each of the example implementations
- 372       ▪ NIST SP 1800-36E: *Risk and Compliance Management* – risk analysis and mapping of trusted IoT  
373 device network-layer onboarding and lifecycle management security characteristics to  
374 cybersecurity standards and recommended practices

375 Depending on your role in your organization, you might use this guide in different ways:

376 **Business decision makers, including chief security and technology officers,** will be interested in the  
377 *Executive Summary, NIST SP 1800-36A*, which describes the following topics:

- 378       ▪ challenges that enterprises face in migrating to the use of trusted IoT device network-layer  
379 onboarding
- 380       ▪ example solutions built at the NCCoE
- 381       ▪ benefits of adopting the example solution

382 **Technology or security program managers** who are concerned with how to identify, understand, assess,  
383 and mitigate risk will be interested in *NIST SP 1800-36B*, which describes what we did and why.

384 Also, Section 4 of *NIST SP 1800-36E* will be of particular interest. Section 4, *Mappings*, maps logical  
385 components of the general trusted IoT device network-layer onboarding and lifecycle management  
386 reference design to security characteristics listed in various cybersecurity standards and recommended  
387 practices documents, including *Framework for Improving Critical Infrastructure Cybersecurity* (NIST  
388 Cybersecurity Framework) and *Security and Privacy Controls for Information Systems and Organizations*  
389 (NIST SP 800-53).

390 You might share the *Executive Summary, NIST SP 1800-36A*, with your leadership team members to help  
391 them understand the importance of using standards-based implementations for trusted IoT device  
392 network-layer onboarding and lifecycle management.

393 **IT professionals** who want to implement similar solutions will find all volumes of the practice guide  
394 useful. You can use the how-to portion of the guide, *NIST SP 1800-36C*, to replicate all or parts of the  
395 builds created in our lab. The how-to portion of the guide provides specific product installation,  
396 configuration, and integration instructions for implementing the example solution. We do not re-create  
397 the product manufacturers' documentation, which is generally widely available. Rather, we show how  
398 we incorporated the products together in our environment to create an example solution. Also, you can

399 use *Functional Demonstrations, NIST SP 1800-36D*, which provides the use cases that have been defined  
 400 to showcase trusted IoT device network-layer onboarding and lifecycle management security  
 401 capabilities and the results of demonstrating these use cases with each of the example  
 402 implementations. Finally, *NIST SP 1800-36E* will be helpful in explaining the security functionality that  
 403 the components of each build provide.

404 This guide assumes that IT professionals have experience implementing security products within the  
 405 enterprise. While we have used a suite of commercial products to address this challenge, this guide does  
 406 not endorse these particular products. Your organization can adopt this solution or one that adheres to  
 407 these guidelines in whole, or you can use this guide as a starting point for tailoring and implementing  
 408 parts of a trusted IoT device network-layer onboarding and lifecycle management solution. Your  
 409 organization’s security experts should identify the products that will best integrate with your existing  
 410 tools and IT system infrastructure. We hope that you will seek products that are congruent with  
 411 applicable standards and recommended practices.

412 A NIST Cybersecurity Practice Guide does not describe “the” solution, but example solutions. We seek  
 413 feedback on the publication’s contents and welcome your input. Comments, suggestions, and success  
 414 stories will improve subsequent versions of this guide. Please contribute your thoughts to  
 415 [iot-onboarding@nist.gov](mailto:iot-onboarding@nist.gov).

## 416 2.1 Typographic Conventions

417 The following table presents typographic conventions used in this volume.

Typeface/Symbol	Meaning	Example
<i>Italics</i>	file names and path names; references to documents that are not hyperlinks; new terms; and placeholders	For language use and style guidance, see the <i>NCCoE Style Guide</i> .
<b>Bold</b>	names of menus, options, command buttons, and fields	Choose <b>File &gt; Edit</b> .
Monospace	command-line input, onscreen computer output, sample code examples, and status codes	<code>mkdir</code>
<b>Monospace Bold</b>	command-line user input contrasted with computer output	<b><code>service sshd start</code></b>
<a href="#">blue text</a>	link to other parts of the document, a web URL, or an email address	All publications from NIST’s NCCoE are available at <a href="https://www.nccoe.nist.gov">https://www.nccoe.nist.gov</a> .

## 418 3 Approach

419 This project builds on the document-based research presented in the NIST Draft Cybersecurity White  
 420 Paper, *Trusted Internet of Things (IoT) Device Network-Layer Onboarding and Lifecycle Management* [2].  
 421 That paper describes key security and other characteristics of a trusted network-layer onboarding  
 422 solution as well as the integration of onboarding with related technologies such as device attestation,  
 423 device communications intent [3][4], and application-layer onboarding. The security and other

424 attributes of the onboarding process that are cataloged and defined in that paper can provide assurance  
425 that the network is not put at risk as new IoT devices are added to it and also that IoT devices are  
426 safeguarded from being taken over by unauthorized networks.

427 To kick off this project, the NCCoE published a Federal Register Notice [\[5\]](#) inviting technology providers  
428 to participate in demonstrating approaches to deploying trusted IoT device network-layer onboarding  
429 and lifecycle management in home and enterprise networks, with the objective of showing how trusted  
430 IoT device network-layer onboarding can practically and effectively enhance the overall security of IoT  
431 devices and, by extension, the security of the networks to which they connect. The Federal Register  
432 Notice invited technology providers to provide products and/or expertise to compose prototypes.  
433 Components sought included network onboarding components and IoT devices that support trusted  
434 network-layer onboarding protocols; authorization services; supply chain integration services; access  
435 points, routers, or switches; components that support device communications intent management;  
436 attestation services; controllers or application services; IoT device lifecycle management services; and  
437 asset management services. Cooperative Research and Development Agreements (CRADAs) were  
438 established with qualified respondents, and teams of collaborators were assembled to build a variety of  
439 implementations.

440 NIST is following an agile methodology of building implementations iteratively and incrementally,  
441 starting with network-layer onboarding and gradually integrating additional capabilities that improve  
442 device and network security throughout a managed device lifecycle. The project team began by  
443 designing a general, protocol-agnostic reference architecture for trusted network-layer onboarding (see  
444 [Section 4](#)) and establishing a laboratory infrastructure at the NCCoE to host implementations (see  
445 [Section 5](#)).

446 Five build teams were established to implement trusted network-layer onboarding prototypes, and a  
447 sixth build team was established to demonstrate multiple builds for factory provisioning activities  
448 performed by an IoT device manufacturer to enable devices to support trusted network-layer  
449 onboarding. Each of the build teams fleshed out the initial architectures of their example  
450 implementations. They then used technologies, capabilities, and components from project collaborators  
451 to begin creating the builds:

- 452     ▪ Build 1 (Wi-Fi Easy Connect, Aruba/HPE) uses components from Aruba, a Hewlett Packard  
453     Enterprise company, to support trusted network-layer onboarding using the Wi-Fi Alliance's Wi-  
454     Fi Easy Connect Specification, Version 2.0 [\[6\]](#) and independent (see [Section 3.3.2](#)) application-  
455     layer onboarding to the Aruba User Experience Insight (UXI) cloud.
- 456     ▪ Build 2 (Wi-Fi Easy Connect, CableLabs, OCF) uses components from CableLabs to support  
457     trusted network-layer onboarding using the Wi-Fi Easy Connect protocol that allows  
458     provisioning of per-device credentials and policy management for each device. Build 2 also uses  
459     components from the Open Connectivity Foundation (OCF) to support streamlined (see [Section](#)  
460     [3.3.2](#)) trusted application-layer onboarding to the OCF security domain.
- 461     ▪ Build 3 (BRSKI, Sandelman Software Works) uses components from Sandelman Software Works  
462     to support trusted network-layer onboarding using the Bootstrapping Remote Secure Key  
463     Infrastructure (BRSKI) [\[7\]](#) protocol and an independent, third-party Manufacturer Authorized  
464     Signing Authority (MASA).

- 465       ▪ Build 4 (Thread [\[8\]](#), Silicon Labs, Kudelski IoT) uses components from Silicon Labs to support  
466       connection to an OpenThread [\[9\]](#) network using pre-shared credentials and components from  
467       Kudelski IoT to support trusted application-layer onboarding to the Amazon Web Services (AWS)  
468       IoT core.
- 469       ▪ Build 5 (BRSKI over Wi-Fi, NquiringMinds) uses components from NquiringMinds to support  
470       trusted network-layer onboarding using the BRSKI protocol over 802.11 [\[10\]](#). Additional  
471       components from NquiringMinds support ongoing, policy-based, continuous assurance and  
472       authorization, as well as device communications intent enforcement.
- 473       ▪ The BRSKI Factory Provisioning Build uses components from NquiringMinds to implement the  
474       factory provisioning flows. The build is implemented on Raspberry Pi devices, where the IoT  
475       secure element is an integrated Infineon Optiga™ SLB 9670 TPM 2.0. The device certificate  
476       authority (CA) is externally hosted on NquiringMinds servers. This build demonstrates activities  
477       for provisioning IoT devices with their initial (i.e., birth—see [Section 3.3](#)) credentials for use with  
478       the BRSKI protocol and for making device bootstrapping information available to device owners.
- 479       ▪ The Wi-Fi Easy Connect Factory Provisioning Build uses Raspberry Pi devices and code from  
480       Aruba and secure storage elements, code, and a CA from SEALSQ, a subsidiary of WISEKey. This  
481       build demonstrates activities for provisioning IoT devices with their birth credentials for use with  
482       the Wi-Fi Easy Connect protocol and for making device bootstrapping information available to  
483       device owners.

484 Each build team documented the architecture and design of its build (see [Appendix C](#), [Appendix D](#),  
485 [Appendix E](#), [Appendix F](#), [Appendix G](#), and [Appendix H](#)). As each build progressed, its team also  
486 documented the steps taken to install and configure each component of the build (see NIST SP 1800-  
487 36C).

488 The project team then designed a set of use case scenarios designed to showcase the builds' security  
489 capabilities. Each build team conducted a functional demonstration of its build by running the build  
490 through the defined scenarios and documenting the results (see NIST SP 1800-36D).

491 The project team also conducted a risk assessment and a security characteristic analysis and  
492 documented the results, including mappings of the security capabilities of the reference solution to both  
493 the *Framework for Improving Critical Infrastructure Cybersecurity* (NIST Cybersecurity Framework) [\[11\]](#)  
494 and Security and Privacy Controls for Information Systems and Organizations ([NIST SP 800-53 Rev. 5](#))  
495 (see NIST SP 1800-36E).

496 Finally, the NCCoE worked with industry and standards-developing organization collaborators to distill  
497 their findings and consider potential enhancements to future support for trusted IoT device network-  
498 layer onboarding (see [Section 6](#) and [Section 7](#)).

### 499 **3.1 Audience**

500 The intended audience for this practice guide includes:

- 501       ▪ IoT device manufacturers, integrators, and vendors
- 502       ▪ Semiconductor manufacturers and vendors
- 503       ▪ Secure storage manufacturers

- 504       ▪ Network equipment manufacturers
- 505       ▪ IoT device owners and users
- 506       ▪ Owners and administrators of networks (both home and enterprise) to which IoT devices
- 507       connect
- 508       ▪ Service providers (internet service providers/cable operators and application platform
- 509       providers)

## 510   **3.2 Scope**

511   This project focuses on the trusted network-layer onboarding of IoT devices in both home and  
512   enterprise environments. Enterprise, consumer, and industrial use cases for trusted IoT device network-  
513   layer onboarding are all considered to be in scope at this time. The project encompasses trusted  
514   network-layer onboarding of IoT devices deployed across different Internet Protocol (IP) based  
515   environments using wired, Wi-Fi, and broadband networking technologies. The project addresses the  
516   onboarding of IP-based devices in the initial phase and will consider using technologies such as Zigbee or  
517   Bluetooth in future phases of this project.

518   The project’s scope also includes security technologies that can be integrated with and enhanced by the  
519   trusted network-layer onboarding mechanism to protect the device and its network throughout the  
520   device’s lifecycle. Examples of these technologies include supply chain management, device attestation,  
521   trusted application-layer onboarding, device communications intent enforcement, device lifecycle  
522   management, asset management, the dynamic assignment of devices to various network segments, and  
523   ongoing device authorization. Aspects of these technologies that are relevant to their integration with  
524   network-layer onboarding are within scope. Demonstration of the general capabilities of these  
525   technologies independent of onboarding is not within the project’s scope. For example, demonstrating a  
526   policy that requires device attestation to be performed before the device will be permitted to be  
527   onboarded would be within scope. However, the details and general operation of the device attestation  
528   mechanism would be out of scope.

## 529   **3.3 Assumptions and Definitions**

530   This project is guided by a variety of assumptions, which are categorized by subsection below.

### 531   **3.3.1 Credential Types**

532   There are several different credentials that may be related to any given IoT device, which makes it  
533   important to be clear about which credential is being referred to. Two types of IoT device credentials are  
534   involved in the network-layer onboarding process: birth credentials and network credentials. Birth  
535   credentials are installed onto the device before it is released into the supply chain; trusted network-  
536   layer onboarding solutions leverage birth credentials to authenticate devices and securely provision  
537   them with their network credentials. If supported by the device and the application service provider,  
538   application-layer credentials may be provisioned to the device after the device performs network-layer

539 onboarding and connects to the network, during the application-layer onboarding process. These  
540 different types of IoT device credentials are defined as follows:

541     ▪ **Birth Credential:** In order to participate in trusted network-layer onboarding, devices must be  
542 equipped with a birth credential, which is sometimes also referred to as a device *birth identity*  
543 or *birth certificate*. A birth credential is a unique, authoritative credential that is generated or  
544 installed into secure storage on the IoT device during the pre-market phase of the device's  
545 lifecycle, i.e., before the device is released for sale. A manufacturer, integrator, or vendor  
546 typically generates or installs the birth credential onto an IoT device in the form of an Initial  
547 Device Identifier (IDevID) [12] and/or a public/private key pair.

548 Birth credentials:

- 549     • are permanent, and their value is independent of context;
  - 550     • enable the trusted network-layer onboarding process while keeping the device  
551 manufacturing process efficient; and
  - 552     • include a unique identity and a secret and can range from simple raw public and private  
553 keys to X.509 certificates that are signed by a trusted authority.
- 554     ▪ **Network Credential:** A network credential is the credential that is provisioned to an IoT device  
555 during network-layer onboarding. The network credential enables the device to connect to the  
556 local network securely. A device's network credential may be changed repeatedly, as needed, by  
557 subsequent invocation of the trusted network-layer onboarding process.

558 Additional types of credentials that may also be associated with an IoT device are:

- 559     ▪ **Application-Layer Credential:** An application-layer credential is a credential that is provisioned  
560 to an IoT device during application-layer onboarding. After an IoT device has performed  
561 network-layer onboarding and connected to a network, it may be provisioned with one or more  
562 application-layer credentials during the application-layer onboarding process. Each application-  
563 layer credential is specific to a given application and is typically unique to the device, and it may  
564 be replaced repeatedly over the course of the device's lifetime.
- 565     ▪ **User Credential:** An IoT device that permits authorized users to access it and restricts access  
566 only to authorized users will have one or more user credentials associated with it. These  
567 credentials are what the users present to the IoT device in order to gain access to it. The user  
568 credential is not relevant during network-layer onboarding and is generally not of interest within  
569 the scope of this project. We include it in this list only for completeness. Many IoT devices may  
570 not even have user credentials associated with them.

571 In order to perform network- and application-layer onboarding, the device being onboarded must  
572 already have been provisioned with birth credentials. A pre-provisioned, unique, authoritative birth  
573 credential is essential for enabling the IoT device to be identified and authenticated as part of the  
574 trusted network-layer onboarding process, no matter what network the device is being onboarded to or  
575 how many times it is onboarded. The value of the birth credential is independent of context, whereas  
576 the network credential that is provisioned during network-layer onboarding is significant only with  
577 respect to the network to which the IoT device will connect. Each application-layer credential that is  
578 provisioned during application-layer onboarding is specific to a given application, and each user  
579 credential is specific to a given user. A given IoT device only ever has one birth credential over the  
580 course of its lifetime, and the value of this birth credential remains unchanged. However, that IoT device

581 may have any number of network, application-layer, and user credentials at any given point in time, and  
582 these credentials may be replaced repeatedly over the course of the device’s lifetime.

### 583 3.3.2 Integrating Security Enhancements

584 Integrating trusted network-layer IoT device onboarding with additional security mechanisms and  
585 technologies can help increase trust in both the IoT device and the network to which it connects.

586 Examples of such security mechanism integrations demonstrated in this project include:

587     ▪ **Trusted Application-Layer Onboarding:** When supported, application-layer onboarding can be  
588 performed automatically after a device has connected to its local network. Trusted application-  
589 layer onboarding enables a device to be securely provisioned with the application-layer  
590 credentials it needs to establish a secure association with a trusted application service. In many  
591 cases, a network’s IoT devices will be so numerous that manually onboarding devices at the  
592 application layer would not be practical; in addition, dependence on manual application-layer  
593 onboarding would leave the devices vulnerable to accidental or malicious misconfiguration. So,  
594 application-layer onboarding, like network-layer onboarding, is fundamental to ensuring the  
595 overall security posture of each IoT device.

596 As part of the application-layer onboarding process, devices and the application services with  
597 which they interact perform mutual authentication and establish an encrypted channel over  
598 which the application service can download application-layer credentials and software to the  
599 device and the device can provide information to the application service, as appropriate.  
600 Application-layer onboarding is useful for ensuring that IoT devices are executing the most up-  
601 to-date versions of their intended applications. It can also be used to establish a secure  
602 association between a device and a trusted lifecycle management service, which will ensure that  
603 the IoT device continues to be patched and updated with the latest firmware and software,  
604 thereby enabling the device to remain trusted throughout its lifecycle.

605 Network-layer onboarding cannot be performed until after network-layer bootstrapping  
606 information has been introduced to the device and the network. This network-layer  
607 bootstrapping information enables the device and the network to mutually authenticate and  
608 establish a secure channel. Analogously, application-layer onboarding cannot be performed until  
609 after application-layer bootstrapping information has been introduced to the device and the  
610 application servers with which they will onboard. This application-layer bootstrapping  
611 information enables the device and the application server to mutually authenticate and  
612 establish a secure channel.

613     • *Streamlined Application-Layer Onboarding*—One potential mechanism for introducing this  
614 application-layer bootstrapping information to the device and the application server is to  
615 use the network-layer onboarding process. The secure channel that is established during  
616 network-layer onboarding can serve as the mechanism for exchanging application-layer  
617 bootstrapping information between the device and the application server. By safeguarding  
618 the integrity and confidentiality of the application-layer bootstrapping information as it is  
619 conveyed between the device and the application server, the trusted network-layer  
620 onboarding mechanism helps to ensure that information that the device and the  
621 application server use to authenticate each other is truly secret and known only to them,  
622 thereby establishing a firm foundation for their secure association. In this way, trusted  
623 network-layer onboarding can provide a secure foundation for trusted application-layer  
624 onboarding. We call an application-layer onboarding process that uses network-layer

- 625 onboarding to exchange application-layer bootstrapping information *streamlined*  
626 application-layer onboarding.
- 627 • ***Independent Application-Layer Onboarding***—An alternative mechanism for introducing  
628 application-layer bootstrapping information to the device is to provide this information to  
629 the device during the manufacturing process. During manufacturing, the IoT device can be  
630 provisioned with software and associated bootstrapping information that enables the  
631 device to mutually authenticate with an application-layer service after it has connected to  
632 the network. This mechanism for performing application-layer onboarding does not rely on  
633 the network-layer onboarding process to provide application-layer bootstrapping  
634 information to the device. All that is required is that the device have connectivity to the  
635 application-layer onboarding service after it has connected to the network. We call an  
636 application-layer onboarding process that does not rely on network-layer onboarding to  
637 exchange application-layer bootstrapping information *independent* application-layer  
638 onboarding.
  - 639 ■ **Segmentation:** Upon connection to the network, a device may be assigned to a particular local  
640 network segment to prevent it from communicating with other network components, as  
641 determined by enterprise policy. The device can be protected from other local network  
642 components that meet or do not meet certain policy criteria. Similarly, other local network  
643 components may be protected from the device if it meets or fails to meet certain policy criteria.  
644 A trusted network-layer onboarding mechanism may be used to convey information about the  
645 device that can be used to determine to which network segment it should be assigned upon  
646 connection. By conveying this information in a manner that protects its integrity and  
647 confidentiality, the trusted network-layer onboarding mechanism helps to increase assurance  
648 that the device will be assigned to the appropriate network segment. Post-onboarding, if a  
649 device becomes untrustworthy, for example because it is found to have software that has a  
650 known vulnerability or misconfiguration, or because it is behaving in a suspicious manner, the  
651 device may be dynamically assigned to a different network segment as a means of quarantining  
652 it, or its network-layer credential can be revoked or deleted.
  - 653 ■ **Ongoing Device Authorization:** Once a device has been network-layer onboarded in a trusted  
654 manner and has possibly performed application-layer onboarding as well, it is important that as  
655 the device continues to operate on the network, it maintains a secure posture throughout its  
656 lifecycle. Ensuring the ongoing security of the device is important for keeping the device from  
657 being corrupted and for protecting the network from a potentially harmful device. Even though  
658 a device is authenticated and authorized prior to being onboarded, it is recommended that the  
659 device be subject to ongoing policy-based authentication and authorization as it continues to  
660 operate on the network. This may include monitoring device behavior and constraining  
661 communications to and from the device as needed in accordance with policy. In this manner, an  
662 ongoing device authorization service can ensure that the device and its operations continue to  
663 be authorized throughout the device’s tenure on the network.
  - 664 ■ **Device Communications Intent Enforcement:** Network-layer onboarding protocols can be used  
665 to securely transmit device communications intent information from the device to the network  
666 (i.e., to transmit this information in encrypted form with integrity protections). After the device  
667 has securely connected to the network, the network can use this device communications intent  
668 information to ensure that the device sends and receives traffic only from authorized locations.  
669 Secure conveyance of device communications intent information, combined with enforcement

670 of it, ensures that IoT devices are constrained to sending and receiving only those  
671 communications that are explicitly required for each device to fulfill its purpose.

672     ▪ **Additional Security Mechanisms:** Although not demonstrated in the implementations that have  
673 been built in this project so far, numerous additional security mechanisms can potentially be  
674 integrated with network-layer onboarding, beginning at device boot-up and extending through  
675 all phases of the device lifecycle. Examples of such mechanisms include integration with supply  
676 chain management tools, device attestation, automated lifecycle management, mutual  
677 attestation, and centralized asset management. Overall, application of these and other security  
678 protections can create a dependency chain of protections. This chain is based on a hardware  
679 root of trust as its foundation and extends up to support the security of the trusted network-  
680 layer onboarding process. The trusted network-layer onboarding process in turn may enable  
681 additional capabilities and provide a foundation that makes them more secure, thereby helping  
682 to ensure the ongoing security of the device and, by extension, the network.

### 683 3.3.3 Device Limitations

684 The security capabilities that any onboarding solution will be able to support will depend in part on the  
685 hardware, processing power, cryptographic modules, secure storage capacity, battery life, human  
686 interface (if any), and other capabilities of the IoT devices themselves, such as whether they support  
687 verification of firmware at boot time, attestation, application-layer onboarding, and device  
688 communications intent enforcement; what onboarding and other protocols they support; and whether  
689 they are supported by supply-chain tools. The more capable the device, the more security capabilities it  
690 should be able to support and the more robustly it should be able to support them. Depending on both  
691 device and onboarding solution capabilities, different levels of assurance may be provided.

### 692 3.3.4 Specifications Are Still Improving

693 Ideally, trusted network-layer onboarding solutions selected for widespread implementation and use  
694 will be openly available and standards-based. Some potential solution specifications are still being  
695 improved. In the meantime, their instability may be a limiting factor in deploying operational  
696 implementations of the proposed capabilities. For example, the details of running BRSKI over Wi-Fi are  
697 not fully specified at this time.

## 698 3.4 Collaborators and Their Contributions

699 Organizations participating in this project submitted their capabilities in response to an open call in the  
700 Federal Register for all sources of relevant security capabilities from academia and industry (vendors  
701 and integrators). Listed below are the respondents with relevant capabilities or product components  
702 (identified as “Technology Partners/Collaborators” herein) who signed a CRADA to collaborate with NIST  
703 in a consortium to build example trusted IoT device network-layer onboarding solution.

704

**Technology Collaborators**

705 [Aruba](#), a Hewlett Packard

[Foundries.io](#)

[Open Connectivity Foundation \(OCF\)](#)

706 Enterprise company

[Kudelski IoT](#)

[Sandelman Software Works](#)

707 [CableLabs](#)

[NquiringMinds](#)

[SEALSQ](#), a subsidiary of WISEKey

708 [Cisco](#)

[NXP Semiconductors](#)

[Silicon Labs](#)

709 Table 3-1 summarizes the capabilities and components provided, or planned to be provided, by each  
710 partner/collaborator.

711 **Table 3-1 Capabilities and Components Provided by Each Technology Partner/Collaborator**

Collaborator	Security Capability or Component Provided
<b>Aruba</b>	Infrastructure for trusted network-layer onboarding using the Wi-Fi Easy Connect protocol and application-layer onboarding to the UXI cloud. IoT devices for use with both Wi-Fi Easy Connect network-layer onboarding and application-layer onboarding. The UXI Dashboard provides for an “always-on” remote technician with near real-time data insights into network and application performance.
<b>CableLabs</b>	Infrastructure for trusted network-layer onboarding using the Wi-Fi Easy Connect protocol. IoT devices for use with both Wi-Fi Easy Connect network-layer onboarding and application-layer onboarding to the OCF security domain.
<b>Cisco</b>	Networking components to support various builds.
<b>Foundries.io</b>	Factory software for providing birth credentials into secure storage on IoT devices and for transferring device bootstrapping information from device manufacturer to device purchaser.
<b>Kudelski IoT</b>	Infrastructure for trusted application-layer onboarding of a device to the AWS IoT core. The service comes with a cloud platform and a software agent that enables secure provisioning of AWS credentials into the secure storage of IoT devices.
<b>NquiringMinds</b>	Infrastructure for trusted network-layer onboarding using BRSKI over 802.11. Service that performs ongoing monitoring of connected devices to ensure their continued authorization (i.e., continuous authorization service), as well as device communications intent enforcement.
<b>NXP Semiconductors</b>	IoT devices with secure storage for use with both Wi-Fi Easy Connect and BRSKI network-layer onboarding. Service for provisioning credentials into secure storage of IoT devices.
<b>Open Connectivity Foundation (OCF)</b>	Infrastructure for trusted application-layer onboarding to the OCF security domain using IoTivity, an open-source software framework that implements the OCF specification.
<b>Sandelman Software Works</b>	Infrastructure for trusted network-layer onboarding using BRSKI. IoT devices for use with BRSKI network-layer onboarding.
<b>SEALSQ, a subsidiary of WISeKey</b>	Secure storage elements, code, and software that simulates factory provisioning of birth credentials to those secure elements on IoT devices in support of both Wi-Fi Easy Connect and BRSKI network-layer onboarding; certificate authority for signing device certificates.
<b>Silicon Labs</b>	Infrastructure for connection to a Thread network that has access to other networks for application-layer onboarding. IoT device with secure storage for use with Thread network connection and application-layer onboarding using Kudelski IoT.

712 Each of these technology partners and collaborators has described the relevant products and  
713 capabilities it brings to this trusted onboarding effort in the following subsections. The NCCoE does not  
714 certify or validate products or services. We demonstrate the capabilities that can be achieved by using  
715 participants' contributed technology.

### 716 3.4.1 Aruba, a Hewlett Packard Enterprise Company

717 Aruba, a Hewlett Packard Enterprise (HPE) company, provides secure, intelligent edge-to-cloud  
718 networking solutions that use artificial intelligence (AI) to automate the network, while harnessing data  
719 to drive powerful business outcomes. With Aruba ESP (Edge Services Platform) and as-a-service options  
720 as part of the HPE GreenLake family, Aruba takes a cloud-native approach to helping customers meet  
721 their connectivity, security, and financial requirements across campus, branch, data center, and remote  
722 worker environments, covering all aspects of wired, wireless local area networking (LAN), and wide area  
723 networking (WAN). Aruba ESP provides unified solutions for connectivity, visibility, and control  
724 throughout the IT-IoT workflow, with the objective of helping organizations accelerate IoT-driven digital  
725 transformation with greater ease, efficiency, and security. To learn more, visit Aruba at  
726 <https://www.arubanetworks.com/>.

#### 727 3.4.1.1 Device Provisioning Protocol

728 [Device Provisioning Protocol \(DPP\)](#), certified under the Wi-Fi Alliance (WFA) as “Easy Connect,” is a  
729 standard developed by Aruba that allows IoT devices to be easily provisioned onto a secure network.  
730 DPP improves security by leveraging Wi-Fi Protected Access 3 (WPA3) to provide device-specific  
731 credentials, enhance certificate handling, and support robust, secure, and scalable provisioning of IoT  
732 devices in any commercial, industrial, government, or consumer application. Aruba implements DPP  
733 through a combination of on-premises hardware and cloud-based services as shown in [Table 3-1](#).

#### 734 3.4.1.2 Aruba Access Point (AP)

735 From their unique vantage as ceiling furniture, [Aruba Wi-Fi 6 APs](#) have an unobstructed overhead view  
736 of all nearby devices. Built-in Bluetooth Low Energy (BLE) and Zigbee 802.15.4 IoT radios, as well as a  
737 flexible USB port, provide IoT device connectivity that allows organizations to address a broad range of  
738 IoT applications with infrastructure already in place, eliminating the cost of gateways and IoT overlay  
739 networks while enhancing IoT security.

740 Aruba's APs enable a DPP network through an existing Service Set Identifier (SSID) enforcing DPP access  
741 control and advertising the Configurator Connectivity Information Element (IE) to attract unprovisioned  
742 clients (i.e., clients that have not yet been onboarded). Paired with Aruba's cloud management service  
743 “Central”, the APs implement the DPP protocol. The AP performs the DPP network introduction protocol  
744 (Connector exchange) with provisioned clients and assigns network roles.

#### 745 3.4.1.3 Aruba Central

746 [Aruba Central](#) is a cloud-based networking solution with AI-powered insights, workflow automation, and  
747 edge-to-cloud security that empowers IT teams to manage and optimize campus, branch, remote, data  
748 center, and IoT networks from a single point of visibility and control. Built on a cloud-native,  
749 microservices architecture, Aruba Central is designed to simplify IT and IoT operations, improve agility,  
750 and reduce costs by unifying management of all network infrastructure.

751 Aruba’s “Central” Cloud DPP service exposes and controls many centralized functions to enable a  
752 seamless integrated end-to-end solution and act as a DPP service orchestrator. The cloud based DPP  
753 service selects an AP to authenticate unprovisioned enrollees (in the event that multiple APs receive the  
754 client *chirps*). The DPP cloud service holds the Configurator signing key and generates Connectors for  
755 enrollees authenticated through an AP.

#### 756 *3.4.1.4 IoT Operations*

757 Available within Aruba Central, the [IoT Operations service](#) extends network administrators’ view into IoT  
758 devices and applications connected to the network. Organizations can gain critical visibility into  
759 previously invisible IoT devices, as well as reduce costs and complexity associated with deploying IoT  
760 applications. IoT Operations comprises three core elements:

- 761       ▪ IoT Dashboard, which provides a granular view of devices connected to Aruba APs, as well as IoT  
762       connectors and applications in use.
- 763       ▪ IoT App Store, a repository of click-and-go IoT applications that interface with IoT devices and  
764       their data.
- 765       ▪ IoT Connector, which provisions multiple applications to be computed at the edge for agile IoT  
766       application support.

#### 767 *3.4.1.5 Client Insights*

768 Part of Aruba Central, AI-powered [Client Insights](#) automatically identifies each endpoint connecting to  
769 the network with up to 99% accuracy. Client Insights discovers and classifies all connected endpoints—  
770 including IoT devices—using built-in machine learning and dynamic profiling techniques, helping  
771 organizations better understand what’s on their networks, automate access privileges, and monitor the  
772 behavior of each endpoint’s traffic flows to more rapidly spot attacks and act.

#### 773 *3.4.1.6 Cloud Auth*

774 Cloud-native network access control (NAC) solution [Cloud Auth](#) delivers time-saving workflows to  
775 configure and manage onboarding, authorization, and authentication policies for wired and wireless  
776 networks. Cloud Auth integrates with an organization’s existing cloud identity store, such as Google  
777 Workspace or Azure Active Directory, to authenticate IoT device information and assign the right level of  
778 network access.

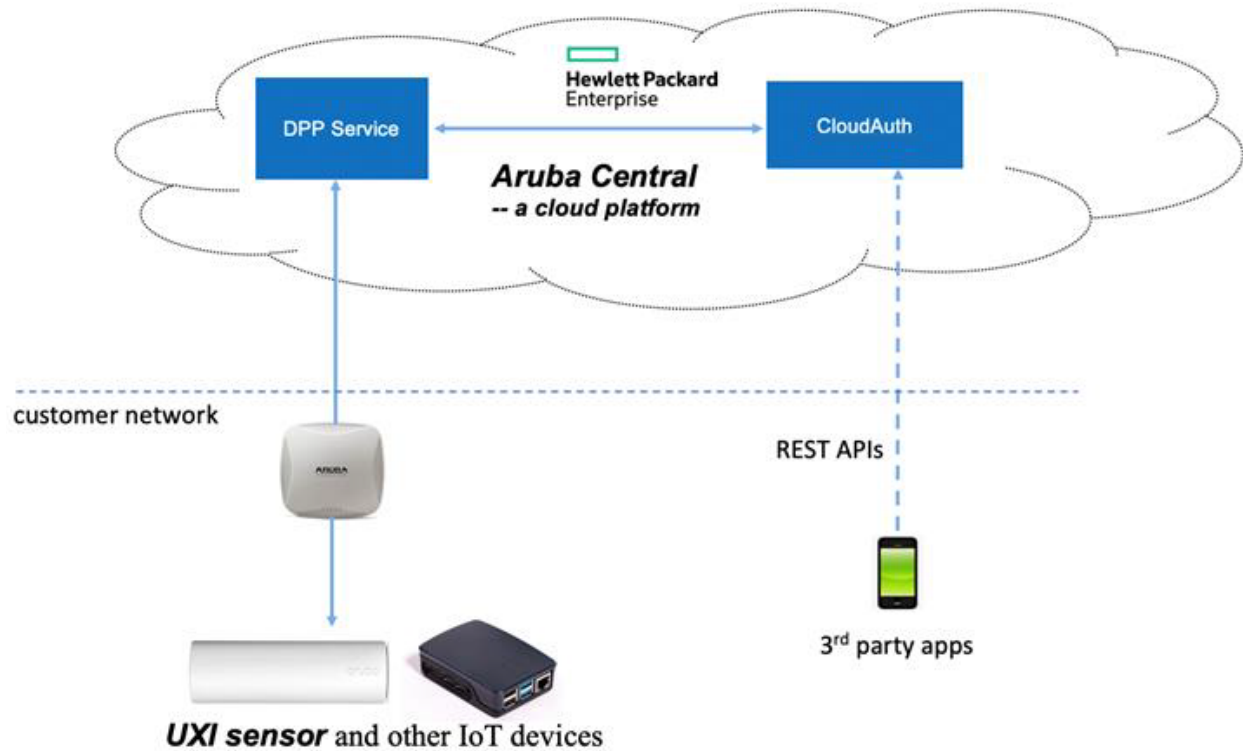

779 Cloud Auth operates as the DPP Authorization server and is the repository for trusted DPP Uniform  
780 Resource Identifiers (URIs) of unprovisioned enrollees. It maintains role information for each  
781 unprovisioned DPP URI and provisioned devices based on unique per-device credential (public key  
782 extracted from Connector). Representational State Transfer (RESTful) application programming  
783 interfaces (APIs) provide extensible capabilities to support third parties, making an easy path for  
784 integration and collaborative deployments.

#### 785 *3.4.1.7 UXI Sensor: DPP Enrollee*

786 User Experience Insight (UXI) sensors continuously monitor end-user experience on customer networks  
787 and provide a simple-to-use cloud-based dashboard to assess networks and applications. The UXI sensor  
788 is onboarded in a zero-touch experience using DPP. Once network-layer onboarding is complete, the UXI

789 sensor performs application-layer onboarding to the Aruba cloud to download a customer-specific  
 790 profile. This profile enables the UXI sensor to perform continuous network testing and monitoring, and  
 791 to troubleshoot network issues that it finds.

792 **Figure 3-1 Aruba/HPE DPP Onboarding Components**

### 793 3.4.2 CableLabs

794 CableLabs is an innovation lab for future-forward research and development (R&D)—a global meeting of  
 795 minds dedicated to building and orchestrating emergent technologies. By convening peers and experts  
 796 to share knowledge, CableLabs' objective is to energize the industry ecosystem for speed and scale. Its  
 797 research facilitates solutions with the goal of making connectivity faster, easier, and more secure, and  
 798 its conferences and events offer neutral meeting points to gain consensus.

799 As part of this project, CableLabs has provided the reference platform for its Custom Connectivity  
 800 architecture for the purpose of demonstrating trusted network-layer onboarding of Wi-Fi devices using  
 801 a variety of credentials. The following components are part of the reference platform.

#### 802 3.4.2.1 Platform Controller

803 The controller provides interfaces and messaging for managing service deployment groups, access  
 804 points with the deployment groups, registration and lifecycle of user services, and the secure  
 805 onboarding and lifecycle management of users' Wi-Fi devices. The controller also exposes APIs for  
 806 integration with third-party systems for the purpose of integrating various business flows (e.g.,  
 807 integration with manufacturing process for device management).

### 808 *3.4.2.2 Custom Connectivity Gateway Agent*

809 The Gateway Agent is a software component that resides on the Wi-Fi AP and gateway. It connects with  
810 the controller to coordinate the Wi-Fi and routing capabilities on the gateway. Specifically, it enforces  
811 the policies and configuration from the controller by managing the lifecycle of the Wi-Fi Extended  
812 Service Set/Basic Service Set (ESS/BSS) on the AP, authentication and credentials of the client devices  
813 that connect to the AP, and service management and routing rules for various devices. It also manages  
814 secure onboarding capabilities like Easy Connect, simple onboarding using a per-device pre-shared key  
815 (PSK), etc. The Gateway agent is provided in the form of an operational Raspberry Pi-based Gateway  
816 that also includes hostapd for Wi-Fi/DPP and open-vswitch for the creation of trust domains and  
817 routing.

### 818 *3.4.2.3 Reference Clients*

819 Three Raspberry Pi-based reference clients are provided. The reference clients have support for WFA  
820 Easy Connect-based onboarding as well as support for different Wi-Fi credentials, including per-device  
821 PSK and 802.1x certificates. One of the reference clients also has support for OCF-based streamlined  
822 application-layer onboarding.

## 823 *3.4.3 Cisco*

824 Cisco Systems, or Cisco, delivers collaboration, enterprise, and industrial networking and security  
825 solutions. The company's cybersecurity team, Cisco Secure, is one of the largest cloud and network  
826 security providers in the world. Cisco's Talos Intelligence Group, the largest commercial threat  
827 intelligence team in the world, is comprised of world-class threat researchers, analysts, and engineers,  
828 and supported by unrivaled telemetry and sophisticated systems. The group feeds rapid and actionable  
829 threat intelligence to Cisco customers, products, and services to help identify new threats quickly and  
830 defend against them. Cisco solutions are built to work together and integrate into your environment,  
831 using the "network as a sensor" and "network as an enforcer" approach to both make your team more  
832 efficient and keep your enterprise secure. Learn more about Cisco at <https://www.cisco.com/go/secure>.

### 833 *3.4.3.1 Cisco Catalyst Switch*

834 A Cisco Catalyst switch is provided to support network connectivity and network segmentation  
835 capabilities.

## 836 *3.4.4 Foundries.io*

837 Foundries.io helps organizations bring secure IoT and edge devices to market faster. The  
838 FoundriesFactory cloud platform offers DevOps teams a secure Linux-based firmware/operating system  
839 (OS) platform with device and fleet management services for connected devices, based on a fixed no-  
840 royalty subscription model. Product development teams gain enhanced security from boot to cloud  
841 while reducing the cost of developing, deploying, and updating devices across their installed lifetime.  
842 The open-source platform interfaces to any cloud and offers Foundries.io customers maximum flexibility  
843 for hardware configuration, so organizations can focus on their intellectual property, applications, and  
844 value add. For more information, please visit <https://foundries.io/>.

#### 845 [3.4.4.1 FoundriesFactory](#)

846 FoundriesFactory is a cloud-based software platform provided by Foundries.io that offers a complete  
847 development and deployment environment for creating secure IoT devices. It provides a set of tools and  
848 services that enable developers to create, test, and deploy custom firmware images, as well as manage  
849 the lifecycle of their IoT devices.

850 Customizable components include open-source secure boot software, the open-source Linux  
851 microPlatform (Lmp) distribution built with Yocto and designed for secure managed IoT and edge  
852 products, secure Over the Air (OTA) update facilities, and a Docker runtime for managing containerized  
853 applications and services. The platform is cross architecture (x86, Arm, and RISC-V) and enables secure  
854 connections to public and private cloud services.

855 Leveraging open standards and open software, FoundriesFactory is designed to simplify and accelerate  
856 the process of developing, deploying, and managing IoT and edge devices at scale, while also ensuring  
857 that they are secure and up to date over the product lifetime.

#### 858 [3.4.5 Kudelski IoT](#)

859 Kudelski IoT is the Internet of Things division of Kudelski Group and provides end-to-end IoT solutions,  
860 IoT product design, and full-lifecycle services to IoT semiconductor and device manufacturers,  
861 ecosystem creators, and end-user companies. These solutions and services leverage the group's 30+  
862 years of innovation in digital business model creation; hardware, software, and ecosystem design and  
863 testing; state-of-the-art security lifecycle management technologies and services; and managed  
864 operation of complex systems.

##### 865 [3.4.5.1 Kudelski IoT keySTREAM™](#)

866 Kudelski IoT keySTREAM is a device-to-cloud, end-to-end solution for securing all the key assets of an IoT  
867 ecosystem during its entire lifecycle. The system provides each device with a unique, immutable,  
868 unclonable identity that forms the foundation for critical IoT security functions like in-factory or [in-field](#)  
869 [provisioning](#), data encryption, authentication, and [secure firmware updates](#), as well as allowing  
870 companies to revoke network access for vulnerable devices if necessary. This ensures that the entire  
871 lifecycle of the device and its data can be managed.

872 In this project, keySTREAM is used to enable trusted application-layer onboarding. It manages the  
873 attestation of devices, ownership, and provisioning of application credentials.

#### 874 [3.4.6 NquiringMinds](#)

875 NquiringMinds provides intelligent trusted systems, combining AI-powered analytics with cyber security  
876 fundamentals. [tdx Volt](#) is the NquiringMinds general-purpose zero-trust services infrastructure platform,  
877 upon which it has built [Cyber tdx](#), a cognitively enhanced cyber defense service designed for IoT. Both  
878 products are the latest iteration of the TDX product family. NquiringMinds is a UK company. Since 2010,  
879 it has been deploying its solutions into smart cities, health care, industrial, agricultural, financial  
880 technology, defense, and security sectors.

881 NquiringMinds collaborates within the open-standards and open-source community. It focuses on the  
882 principle of continuous assurance: the ability to continually reassess security risk by intelligently

883 reasoning across the hard and soft information sources available. NquiringMinds' primary contributions  
884 to this project, described in the subsections below, are being made available as open source.

#### 885 *3.4.6.1 NquiringMinds' BRSKI Protocol Implementation*

886 NquiringMinds has open sourced their software implementation of IETF's Bootstrapping Remote Secure  
887 Key Infrastructure (BRSKI) protocol, which provides a solution for secure zero-touch (automated)  
888 bootstrap of new (unconfigured) devices. This implementation includes the necessary adaptations for  
889 BRSKI to work with Wi-Fi networks.

890 The open source BRSKI implementation is available under an Apache 2.0 license at:

891 <https://github.com/nqminds/brski>

#### 892 *3.4.6.2 TrustNetZ*

893 NquiringMinds has open sourced the TrustNetZ (Zero Trust Networking) software stack which sits on top  
894 of their BRSKI implementation. TrustNetZ embodies the network onboarding and lifecycle management  
895 concepts into an easy to replicate demonstrator which includes the IoT device, the router, the router  
896 onboarding, the registrar, the manufacturer, the manufacturer provisioning, policy enforcement and  
897 continuous assurance servers.

898 This software also encapsulates NquiringMinds' continuous assurance capability, enhancing the security  
899 of the network by continually assessing whether connected IoT devices meet the policy requirements of  
900 the network. The software also includes a flexible, verifiable credential-based policy framework, which  
901 can rapidly be adapted to model different security and business model scenarios. The implementation  
902 models networking onboarding flows with EAP-TLS Wi-Fi certificates.

903 The open source TrustNetZ implementation is available under an Apache 2.0 license at:

904 <https://github.com/nqminds/trustnetz>

#### 905 *3.4.6.3 edgeSEC*

906 [edgeSEC](#) is an open-source, OpenWrt-based implementation of an intelligent secure router. It  
907 implements, on an open stack, the key components needed to implement both trusted onboarding and  
908 continuous assurance of devices. It contains an implementation of the Internet Engineering Task Force  
909 (IETF) BRSKI protocols, with the necessary adaptations for wireless onboarding, fully integrated into an  
910 open operational router. It additionally implements device communications intent constraints (IETF  
911 Manufacturer Usage Description [MUD]) and behavior monitoring (IoTSEF ManySecured) that support  
912 some of the more enhanced trusted onboarding use cases. EdgeSEC additionally provides the platform  
913 for an asynchronous control plane for the continuous management of multiple routers and a general-  
914 purpose policy evaluation point, which can be used to demonstrate the breadth of onboarding and  
915 monitoring use cases that can be supported.

916 EdgeSEC is not directly used in the build that was demonstrated for this project, but it contains critical  
917 pieces of code that have been adapted in a simplified manner for the TrustNetZ implementation.

918 The open source edgeSEC implementation is available under an Apache 2.0 license at:

919 <https://github.com/nqminds/edgesec>

#### 920 [3.4.6.4 tdx Volt](#)

921 tdx Volt is NquiringMinds' zero-trust infrastructure platform. It encapsulates identity management,  
922 credential management, service discovery, and smart policy evaluation. This platform is designed to  
923 simplify the end-to-end demonstration of the trusted onboarding process and provides tools for use on  
924 the IoT device, the router, applications, and clouds. Tdx Volt is used by the TrustNetZ demonstrator as a  
925 verifiable credential issuer and verifier.

926 Tdx Volt is an NquiringMinds' product. Documented working implementation are available at:  
927 <https://docs.tdxvolt.com/en/introduction>

#### 928 [3.4.6.5 Reference Hardware](#)

929 For demonstration purposes the NquiringMinds components can be deployed using the following  
930 hardware:

##### 931 **Compute hosts: Raspberry Pi 4**

932 <https://www.raspberrypi.com/products/raspberry-pi-4-model-b/>. The Raspberry Pis are used to host  
933 the IoT client device, the router, and all additional compute services. Other Raspberry Pi models are also  
934 likely to work but have not been tested.

##### 935 **TPM/Secure Element**

936 The secure storage for the IoT device (used in network-layer onboarding and factory provisioning) is  
937 provided by an Infineon Optiga™ SLB 9670 TPM 2.0, integrated through a Geek Pi TPM hat.  
938 [https://www.infineon.com/dgdl/Infineon-OPTIGA\\_SLx\\_9670\\_TPM\\_2.0\\_Pi\\_4-ApplicationNotes-v07\\_19-EN.pdf?fileId=5546d4626c1f3dc3016c3d19f43972eb](https://www.infineon.com/dgdl/Infineon-OPTIGA_SLx_9670_TPM_2.0_Pi_4-ApplicationNotes-v07_19-EN.pdf?fileId=5546d4626c1f3dc3016c3d19f43972eb).

940 A working version of the code is also available utilizing the SEALSQ Secure element  
941 <https://www.sealsq.com/semiconductors/vaultic-secure-elements/vaultic-40x>.

#### 942 [3.4.7 NXP Semiconductors](#)

943 NXP Semiconductors focuses on secure connectivity solutions for embedded applications, NXP is  
944 impacting the automotive, industrial, and IoT, mobile, and communication infrastructure markets. Built  
945 on more than 60 years of combined experience and expertise, the company has approximately 31,000  
946 employees in more than 30 countries. Find out more at <https://www.nxp.com/>.

##### 947 [3.4.7.1 EdgeLock SE050 secure element](#)

948 The EdgeLock SE050 secure element (SE) product family offers strong protection against the latest  
949 attack scenarios and an extended feature set for a broad range of IoT use cases. This ready-to-use  
950 secure element for IoT devices provides a root of trust at the silicon level and delivers real end-to-end  
951 security – from edge to cloud – with a comprehensive software package for integration into any type of  
952 device.

### 953 3.4.7.2 *EdgeLock 2GO*

954 EdgeLock 2GO is the NXP service platform designed for easy and secure deployment and management  
955 of IoT devices. This flexible IoT service platform lets the device manufacturers and service providers  
956 choose the appropriate options to optimize costs while benefiting from an advanced level of device  
957 security. The EdgeLock 2GO service provisions the cryptographic keys and certificates into the hardware  
958 root of trust of the IoT devices and simplifies the onboarding of the devices to the cloud.

### 959 3.4.7.3 *i.MX 8M family*

960 The i.MX 8M family of applications processors based on Arm® Cortex®-A53 and Cortex-M4 cores provide  
961 advanced audio, voice, and video processing for applications that scale from consumer home audio to  
962 industrial building automation and mobile computers. It includes support for secure boot, secure debug,  
963 and lifecycle management, as well as integrated cryptographic accelerators. The development boards  
964 and Linux Board Support Package enablement provide out-of-the-box integration with an external SE050  
965 secure element.

## 966 3.4.8 Open Connectivity Foundation (OCF)

967 OCF is a standards-developing organization that has had contributions and participation from over 450+  
968 member organizations representing the full spectrum of the IoT ecosystem, from chip makers to  
969 consumer electronics manufacturers, silicon enablement software platform and service providers, and  
970 network operators. The OCF specification is an International Organization for  
971 Standardization/International Electrotechnical Commission (ISO/IEC) internationally recognized standard  
972 that was built in tandem with an open-source reference implementation called IoTivity. Additionally,  
973 OCF provides an in-depth testing and certification program.

### 974 3.4.8.1 *IoTivity*

975 OCF has contributed open-source code from IoTivity that demonstrates the advantage of secure  
976 network-layer onboarding and implements the WFA's Easy Connect to power a seamless bootstrapping  
977 of secure and trusted application-layer onboarding of IoT devices with minimal user interaction.

978 This code includes the interaction layer, called the OCF Diplomat, which handles secure communication  
979 between the DPP-enabled access point and the OCF application layer. The OCF onboarding tool (OBT) is  
980 used to configure and provision devices with operational credentials. The OCF reference  
981 implementation of a basic lamp is used to demonstrate both network- and application-layer onboarding  
982 and to show that once onboarded and provisioned, the OBT can securely interact with the lamp.

## 983 3.4.9 Sandelman Software Works

984 Sandelman Software Works (SSW) provides consulting and software design services in the areas of  
985 systems and network security. A complete stack company, SSW provides consulting and design services  
986 from the hardware driver level up to Internet Protocol Security (IPsec), Transport Layer Security (TLS),  
987 and cloud database optimization. SSW has been involved with the IETF since the 1990s, now dealing  
988 with the difficult problem of providing security for IoT systems. SSW leads standardization efforts  
989 through a combination of running code and rough consensus.

### 990 *3.4.9.1 Minerva Highway IoT Network-Layer Onboarding and Lifecycle Management* 991 *System*

992 The Highway component is a cloud-native component operated by the device manufacturer (or its  
993 authorized designate). It provides the Request for Comments (RFC) 8995 [7] specified Manufacturer  
994 Authorized Signing Authority (MASA) for the BRSKI onboarding mechanism.

995 Highway is an asset manager for IoT devices. In its asset database it maintains an inventory of devices  
996 that have been manufactured, what type they are, and who the current owner of the device is (if it has  
997 been sold). Highway does this by taking control of the complete identity lifecycle of the device. It can aid  
998 in provisioning new device identity certificates (IDeVIDs) by collecting Certificate Signing Requests and  
999 returning certificates, or by generating the new identities itself. This is consistent with Section 4.1.2.1  
1000 (On-device private key generation) and Section 4.1.2.2 (Off-device private key generation) of  
1001 <https://www.ietf.org/archive/id/draft-irtf-t2trg-taxonomy-manufacturer-anchors-00.html>.

1002 Highway can act as a standalone three-level private-public key infrastructure (PKI). Integrations with  
1003 Automatic Certificate Management Environment (RFC 8555) allow it to provision certificates from an  
1004 external PKI using the DNS-01 challenge in Section 8.4 of [https://www.rfc-](https://www.rfc-editor.org/rfc/rfc8555.html#section-8.4)  
1005 [editor.org/rfc/rfc8555.html#section-8.4](https://www.rfc-editor.org/rfc/rfc8555.html#section-8.4). Hardware integrations allow for the private key operations to  
1006 be moved out of the main CPU. However, the needs of a busy production line in a factory would require  
1007 continuous access to the hardware offload.

1008 In practice, customers put the subordinate CA into Highway, which it needs to sign new IDeVIDs, and put  
1009 the trust anchor private CA into a hardware security module (HSM).

1010 Highway provides a BRSKI-MASA interface running on a public TCP/HTTPS port (usually 443 or 9443).  
1011 This service requires access to the private key associated to the anchor that has been “baked into” the  
1012 Pledge device during manufacturing. The Highway instance that speaks to the world in this way does not  
1013 have to be the same instance that signs IDeVID certificates, and there are significant security advantages  
1014 to separating them. Both instances do need access to the same database servers, and there are a variety  
1015 of database replication techniques that can be used to improve resilience and security.

1016 As IDeVIDs do not expire, Highway does not presently include any mechanism to revoke IDeVIDs, nor  
1017 does it provide Certificate Revocation Lists (CRLs) or Online Certificate Status Protocol (OCSP). It is  
1018 unclear how those mechanisms can work in practice.

1019 Highway supports two models. In the Sales Integration model, the intended owner is known in advance.  
1020 This model requires customer-specific integrations, which often occur at the database level through  
1021 views or other SQL tools. In the trust on first use (TOFU) model, the first customer to claim a product  
1022 becomes its owner.

### 1023 *3.4.10 SEALSQ, a subsidiary of WISeKey*

1024 WISeKey International Holding Ltd. (WISeKey) is a cybersecurity company that deploys digital identity  
1025 ecosystems and secures IoT solution platforms. It operates as a Swiss-based holding company through  
1026 several operational subsidiaries, each dedicated to specific aspects of its technology portfolio.

1027 SEALSQ is the subsidiary of the group that focuses on designing and selling secure microcontrollers, PKI,  
1028 and identity provisioning services while developing post-quantum technology hardware and software  
1029 products. SEALSQ products and solutions are used across a variety of applications today, from multi-  
1030 factor authentication devices, home automation systems, and network infrastructure, to automotive,  
1031 industrial automation, and control systems.

### 1032 [3.4.11 VaultIC408](#)

1033 The VaultIC408 secure element combines hardware-based key storage with cryptographic accelerators  
1034 to provide a wide array of cryptographic features including identity, authentication, encryption, key  
1035 agreement, and data integrity. It protects against hardware attacks such as micro-probing and side  
1036 channels.

1037 The fundamental cryptography of the VaultIC family includes NIST-recommended algorithms and key  
1038 lengths. Each of these algorithms, Elliptic Curve Cryptography (ECC), Rivest-Shamir-Adleman (RSA), and  
1039 Advanced Encryption Standard (AES), is implemented on-chip and uses on-chip storage of the secret key  
1040 material so the secrets are always protected in the secure hardware.

1041 The secure storage and cryptographic acceleration support use cases like network and IoT end node  
1042 security, platform security, secure boot, secure firmware download, secure communication or TLS, data  
1043 confidentiality, encryption key storage, and data integrity.

#### 1044 [3.4.11.1 INeS Certificate Management System \(CMS\)](#)

1045 SEALSQ's portfolio includes INeS, a managed PKI-as-a-service solution. INeS leverages the WISEKey  
1046 Webtrust-accredited trust services platform, a Matter approved Product Attestation Authority (PAA),  
1047 and custom CAs. These PKI technologies support large-scale IoT deployments, where IoT endpoints will  
1048 require certificates to establish their identities. The INeS CMS platform provides a secure, scalable, and  
1049 manageable trust model.

1050 INeS CMS provides certificate management, CA management, public cloud integration and automation,  
1051 role-based access control (RBAC), and APIs for custom implementations.

### 1052 [3.4.12 Silicon Labs](#)

1053 [Silicon Labs](#) provides products in the area of secure, intelligent wireless technology for a more  
1054 connected world. Securing IoT is challenging. It's also mission critical. The challenge of protecting  
1055 connected devices against frequently surfacing IoT security vulnerabilities follows device makers  
1056 throughout the entire product lifecycle. Protecting products in a connected world is a necessity as  
1057 customer data and modern online business models are increasingly targets for costly hacks and  
1058 corporate brand damage. To stay secure, device makers need an underlying security platform in the  
1059 hardware, software, network, and cloud. Silicon Labs offers security products with features that address  
1060 escalating IoT threats, with the goal of reducing the risk of IoT ecosystem security breaches and the  
1061 compromise of intellectual property and revenue loss from counterfeiting.

1062 For this project, Silicon Labs has provided a host platform for the OpenThread border router (OTBR), a  
1063 Thread radio transceiver, and an IoT device to be onboarded to the AWS cloud service and that  
1064 communicates using the Thread wireless protocol.

### 1065 [3.4.12.1 OpenThread Border Router Platform](#)

1066 A Raspberry Pi serves as host platform for the OTBR. The OTBR forms a Thread network and acts as a  
 1067 bridge between the Thread network and the public internet, allowing the IoT device that communicates  
 1068 using the Thread wireless protocol and that is to be onboarded communicate with cloud services. The  
 1069 OTBR's connection to the internet can be made through either Wi-Fi or ethernet. Connection to the  
 1070 SLWSTK6023A (see [Section 3.4.12.2](#)) is made through a USB serial port.

### 1071 [3.4.12.2 SLWSTK6023A Thread Radio Transceiver](#)

1072 The SLWSTK6023A (Wireless starter kit) acts as a Thread radio transceiver or radio coprocessor (RCP).  
 1073 This allows the OTBR host platform to form and communicate with a Thread network.

### 1074 [3.4.12.3 xG24-DK2601B Thread "End" Device](#)

1075 The xG24-DK2601B is the IoT device that is to be onboarded to the cloud service (AWS). It  
 1076 communicates using the Thread wireless protocol. Communication is bridged between the Thread  
 1077 network and the internet by the OTBR.

### 1078 [3.4.12.4 Kudelski IoT keySTREAM™](#)

1079 The Kudelski IoT keySTREAM solution is described more fully in [Section 3.4.5.1](#). It is a cloud service  
 1080 capable of verifying the hardware-based secure identity certificate chain associated with the xG24-  
 1081 DK2601B component described in [Section 3.4.12.3](#) and delivering a new certificate chain that can be  
 1082 refreshed or revoked as needed to assist with lifecycle management. The certificate chain is used to  
 1083 authenticate the xG24-DK2601B device to the cloud service (AWS).

1084 Figure 3-2 shows the relationships among the components provided by Silicon Labs and Kudelski that  
 1085 support the trusted application-layer onboarding of an IoT device that communicates via the Thread  
 1086 protocol to AWS IoT.

1087 **Figure 3-2 Components for Onboarding an IoT Device that Communicates Using Thread to AWS IoT**

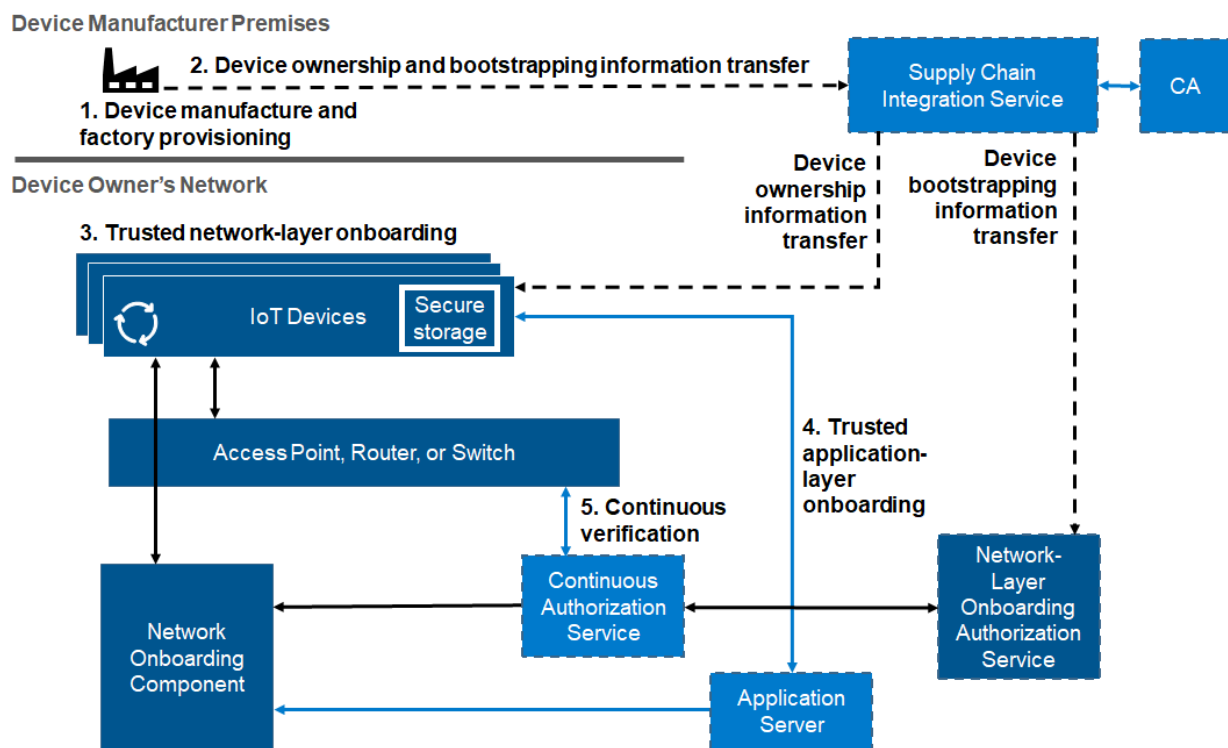

## 1088 4 Reference Architecture

1089 Figure 4-1 depicts the reference architecture to demonstrate trusted IoT device network-layer  
 1090 onboarding and lifecycle management used throughout this Practice Guide. This architecture shows a  
 1091 high-level, protocol-agnostic, and generic approach to trusted network-layer onboarding. It represents  
 1092 the basic components and processes, regardless of the network-layer onboarding protocol used and the  
 1093 particular device lifecycle management activities supported.

1094 When implementing this architecture, an organization can follow different steps and use different  
 1095 components. The exact steps that are performed may not be in the same order as the steps in the  
 1096 logical reference architecture, and they may use components that do not have a one-to-one  
 1097 correspondence with the logical components in the logical reference architecture. In Appendices C, D, E,  
 1098 F and G we present the architectures for builds 1, 2, 3, 4 and 5, each of which is an instantiation of this  
 1099 logical reference architecture. Those build-specific architectures are more detailed and are described in  
 1100 terms of specific collaborator components and trusted network-layer onboarding protocols.

1101 **Figure 4-1 Trusted IoT Device Network-Layer Onboarding and Lifecycle Management Logical Reference**  
 1102 **Architecture**

1103 There are five high-level processes to carry out this architecture, as labeled in Figure 4-1. These five  
 1104 processes are as follows:

- 1105 1. **Device manufacture and factory provisioning** – the activities that the IoT device manufacturer  
 1106 performs to prepare the IoT device so that it is capable of network- and application-layer  
 1107 onboarding ([Figure 4-2](#), [Section 4.1](#)).

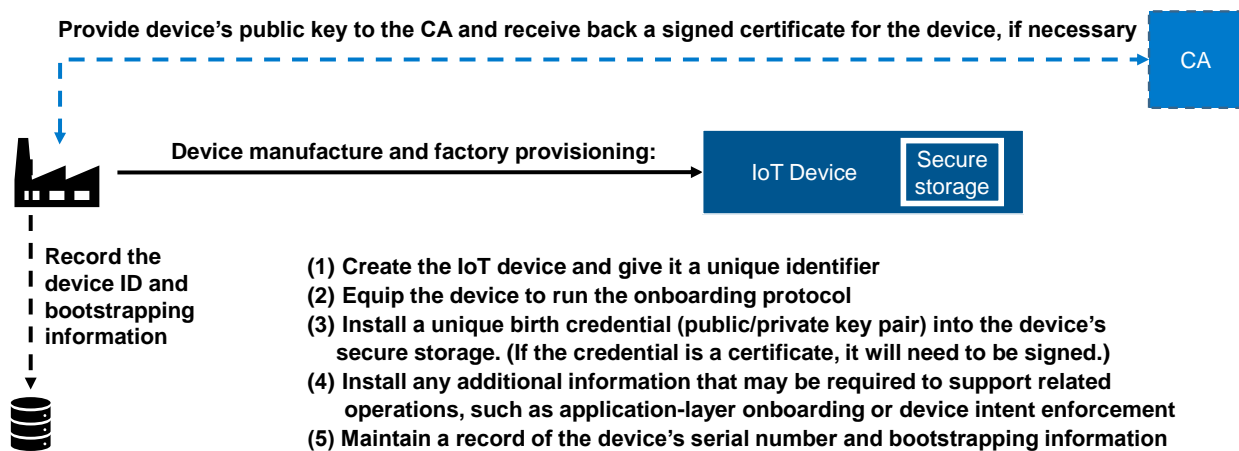

- 1108        2. **Device ownership and bootstrapping information transfer** – the transfer of IoT device  
1109 ownership and bootstrapping information from the manufacturer to the device and/or the  
1110 device’s owner that enables the owner or an entity authorized by the owner to onboard the  
1111 device securely. The component in Figure 4-1 labeled “Supply Chain Integration Service”  
1112 represents the mechanism used to accomplish this information transfer ([Figure 4-3](#), [Section 4.2](#)).
- 1113        3. **Trusted network-layer onboarding** – the interactions that occur between the network-layer  
1114 onboarding component and the IoT device to mutually authenticate, confirm authorization,  
1115 establish a secure channel, and provision the device with its network credentials ([Figure 4-4](#),  
1116 [Section 4.3](#)).
- 1117        4. **Trusted application-layer onboarding** – the interactions that occur between a trusted  
1118 application server and the IoT device to mutually authenticate, establish a secure channel, and  
1119 provision the device with application-layer credentials ([Figure 4-5](#), [Section 4.4](#)).
- 1120        5. **Continuous verification** – ongoing, policy-based verification and authorization checks on the IoT  
1121 device to support device lifecycle monitoring and control ([Figure 4-6](#), [Section 4.5](#)).

1122 Figure 4-1 uses two colors. The dark-blue components are central to supporting trusted network-layer  
1123 onboarding itself. The light-blue components support the other aspects of the architecture. Each of the  
1124 five processes is explained in more detail in the subsections below.

## 1125 **4.1 Device Manufacture and Factory Provisioning Process**

1126 [Figure 4-2](#) depicts the device manufacture and factory provisioning process in more detail. As shown in  
1127 [Figure 4-2](#), the manufacturer is responsible for creating the IoT device and provisioning it with the  
1128 necessary hardware, software, and birth credentials so that it is capable of network-layer onboarding.  
1129 The IoT device should be manufactured with a secure root of trust as a best practice, possibly as part of  
1130 a secure manufacturing process, particularly when outsourced. Visibility and control over the  
1131 provisioning process and manufacturing supply chain, particularly for outsourced manufacturing, is  
1132 critical in order to mitigate the risk of compromise in the supply chain, which could lead to the  
1133 introduction of compromised devices. The CA component is shown in light blue in [Figure 4-2](#) because its  
1134 use is optional and depends on the type of credential that is being provisioned to the device (i.e.,  
1135 whether it is an 802.1AR certificate).

1136 Figure 4-2 IoT Device Manufacture and Factory Provisioning Process

1137 At a high level, the steps that the manufacturer or an integrator performs as part of this preparation  
 1138 process, as shown in Figure 4-2, are as follows:

- 1139 1. Create the IoT device and assign it a unique identifier (e.g., a serial number). Equip the device  
 1140 with secure storage.
- 1141 2. Equip the device to run a specific network-layer onboarding protocol (e.g., Wi-Fi Easy Connect,  
 1142 BRSKI, Thread Mesh Commissioning Protocol (MeshCoP) [8]). This step includes ensuring that  
 1143 the device has the software/firmware needed to run the onboarding protocol as well as any  
 1144 additional information that may be required.
- 1145 3. Generate or install the device's unique birth credential into the device's secure storage. [Note:  
 1146 using a secure element that has the ability to autonomously generate private/public root key  
 1147 pairs is inherently more secure than performing credential injection, which has the potential to  
 1148 expose the private key.] The birth credential includes information that must be kept secret (i.e.,  
 1149 the device's private key) because it is what enables the device's identity to be authenticated.  
 1150 The contents of the birth credential will depend on what network-layer onboarding protocol the  
 1151 device supports. For example:
  - 1152 a. If the device runs the Wi-Fi Easy Connect protocol, its birth credential will take the form  
 1153 of a unique private key, which has an associated DPP URI that includes the  
 1154 corresponding public key and possibly additional information such as Wi-Fi channel and  
 1155 serial number.
  - 1156 b. If the device runs the BRSKI protocol, its birth credential takes the form of an 802.1AR  
 1157 certificate that gets installed as the device's IDevID and corresponding private key. The  
 1158 IDevID includes the device's public key, the location of the MASA, and trust anchors that  
 1159 can be used to verify vouchers signed by the MASA. The 802.1AR certificate needs to be  
 1160 signed by a trusted signing authority prior to installation, as shown in Figure 4-2.
- 1161 4. Install any additional information that may be required to support related capabilities that are  
 1162 enabled by network-layer onboarding. The specific contents of the information that gets

1163 installed on the device will vary according to what capabilities it is intended to support. For  
1164 example, if the device supports:

1165 a. **streamlined application-layer onboarding** (see [Section 3.3.2](#)), then the bootstrapping  
1166 information that is required to enable the device and a trusted application server to find  
1167 and mutually authenticate each other and establish a secure association will be stored  
1168 on the device. This is so it can be sent to the network during network-layer onboarding  
1169 and used to automatically perform application-layer onboarding after the device has  
1170 securely connected to the network. The Wi-Fi Easy Connect protocol, for example, can  
1171 include such application-layer bootstrapping information as third-party information in  
1172 its protocol exchange with the network, and Build 2 (i.e., the Wi-Fi Easy Connect,  
1173 CableLabs, OCF build) demonstrates use of this mechanism to support streamlined  
1174 application-layer onboarding.

1175 Note, however, that a device may still be capable of performing independent [see  
1176 Section 3.3.2] application-layer onboarding even if the application-layer onboarding  
1177 information is not exchanged as part of the network-layer onboarding protocol. The  
1178 application that is installed on the device, i.e., the application that the device executes  
1179 to fulfill its purpose, may include application-layer bootstrapping information that  
1180 enables it to perform application-layer onboarding when it begins executing. Build 1  
1181 (i.e., the Wi-Fi Easy Connect, Aruba/HPE build) demonstrates independent application-  
1182 layer onboarding.

1183 b. **device communications intent**, then the URI required to enable the network to locate  
1184 the device's intent information may be stored on the device so that it can be sent to the  
1185 network during network-layer onboarding. After the device has securely connected to  
1186 the network, the network can use this device communications intent information to  
1187 ensure that the device sends and receives traffic only from authorized locations.

1188 5. Maintain a record of the device's serial number (or other uniquely identifying information) and  
1189 the device's bootstrapping information. The manufacturer will take note of the device's ID and  
1190 its bootstrapping information and store these. Eventually, when the device is sold, the  
1191 manufacturer will need to provide the device's owner with its bootstrapping information. The  
1192 contents of the device's bootstrapping information will depend on what network-layer  
1193 onboarding protocol the device supports. For example:

1194 a. If the device runs the Wi-Fi Easy Connect protocol, its bootstrapping information is the  
1195 DPP URI that is associated with its private key.

1196 b. If the device runs the BRSKI protocol, its bootstrapping information is its 802.1AR  
1197 certificate.

## 1198 4.2 Device Ownership and Bootstrapping Information Transfer Process

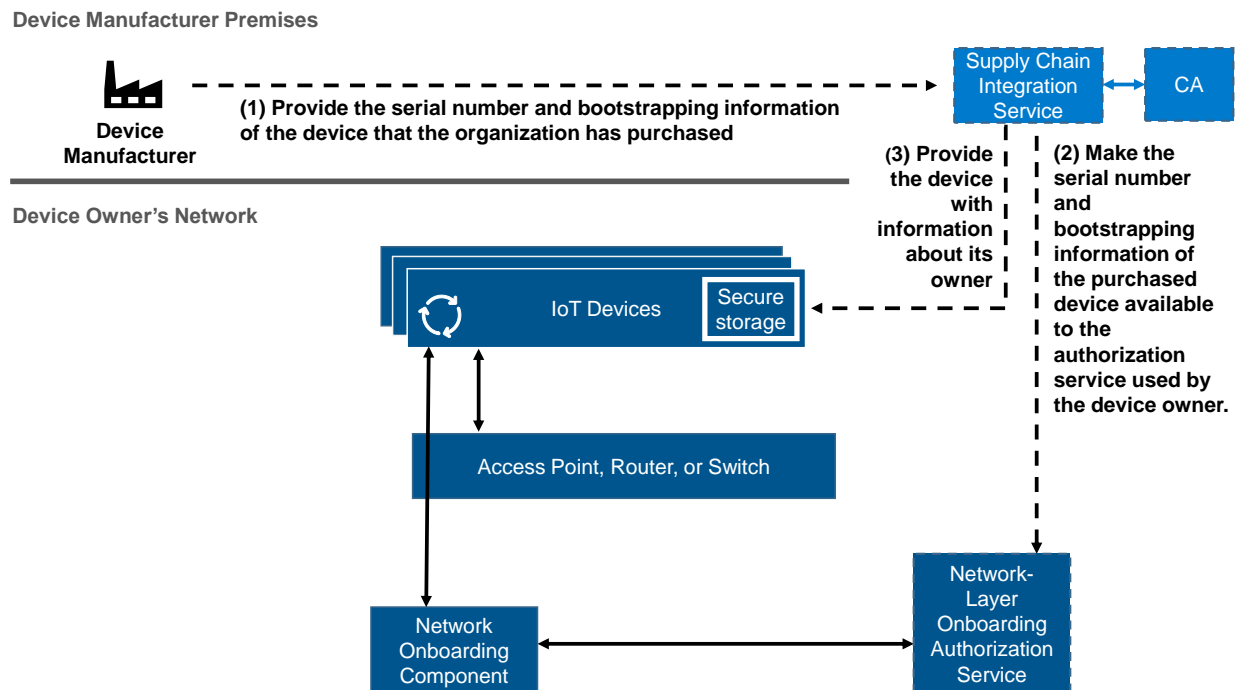

1199 Figure 4-3 depicts the activities that are performed to transfer device bootstrapping information from  
1200 the device manufacturer to the device owner, as well as to transfer device ownership information to the

1201 device itself, if appropriate. A high-level summary of these activities is described in the steps labeled A,  
 1202 B, and C.

1203 The figure uses two colors. The dark-blue components are those used in the network-layer onboarding  
 1204 process. They are the same components as those depicted in the trusted network-layer onboarding  
 1205 process diagram provided in [Figure 4-4](#). The light-blue components and their accompanying steps depict  
 1206 the portion of the diagram that is specific to device ownership and bootstrapping information transfer  
 1207 activities.

1208 **Figure 4-3 Device Ownership and Bootstrapping Information Transfer Process**

1209 These steps are as follows:

- 1210 1. The device manufacturer makes the device serial number, bootstrapping information, and  
 1211 ownership information available so that the organization or individual who has purchased the  
 1212 device will have the device's serial number and bootstrapping information, and the device itself  
 1213 can be informed of who its owner is. In Figure 4-3, the manufacturer is shown sending this  
 1214 information to the supply chain integration service, which ensures that the necessary  
 1215 information ultimately reaches the device owner's authorization service as well as the device  
 1216 itself, if appropriate. (This description of the process is deliberately simple in order to enable it  
 1217 to be general enough that it applies to a variety of network-layer onboarding protocols.) In  
 1218 reality, the supply chain integration service mechanism for forwarding this bootstrapping  
 1219 information from the manufacturer to the owner may take many forms. For example, when  
 1220 BRSKI is used, the manufacturer sends the device serial number and bootstrapping information  
 1221 to a MASA that both the device and its owner trust. When other network-layer onboarding  
 1222 protocols are used, the device manufacturer may provide the device owner with this  
 1223 bootstrapping information directly by uploading this information to the owner's portion of a

1224 trusted cloud. Such a mechanism is useful for the case in which the owner is a large enterprise  
1225 that has made a bulk purchase of many IoT devices. In this case, the manufacturer can upload  
1226 the information for hundreds or thousands of IoT devices to the supply chain integration service  
1227 at once. We call this the enterprise use case. Alternatively, the device manufacturer may  
1228 provide this information to the device owner indirectly by including it on or in the packaging of  
1229 an IoT device that is sold at retail. We call this the consumer use case.

1230 The contents of the device bootstrapping information will also vary according to the network-  
1231 layer onboarding protocol that the device supports. For example, if the device supports the Wi-  
1232 Fi Easy Connect network-layer onboarding protocol, the bootstrapping information will consist  
1233 of the device's DPP URI. If the device supports the BRSKI network-layer onboarding protocol,  
1234 bootstrapping information will consist of the device's IDevID (i.e., its 802.1AR certificate).

1235 2. The supply chain integration service forwards the device serial number and bootstrapping  
1236 information to an authorization service that has connectivity to the network-layer onboarding  
1237 component that will onboard the device (i.e., to a network-layer onboarding component that  
1238 belongs either to the device owner or to an entity that the device owner has authorized to  
1239 onboard the device). The network-layer onboarding component will use the device's  
1240 bootstrapping information to authenticate the device and verify that it is expected and  
1241 authorized to be onboarded to the network. Again, this forwarding may take many forms, e.g.,  
1242 enterprise use case or consumer use case, and use a variety of different mechanisms within  
1243 each use case type, e.g., information moved from one location to another in the device owner's  
1244 portion of a trusted cloud, information transferred via a standardized protocol operating  
1245 between the MASA and the onboarding network's domain registrar, or information scanned  
1246 from a QR code on device packaging using a mobile app. In the case in which BRSKI is used, a  
1247 certificate authority is consulted to help validate the signature of the 802.1AR certificate that  
1248 comprises the device bootstrapping information.

1249 3. The supply chain integration service may also provide the device with information about who its  
1250 owner is. Knowing who its owner is enables the device to ensure that the network that is trying  
1251 to onboard it is authorized to do so, because it is assumed that if a network owns a device, it is  
1252 authorized to onboard it. The mechanisms for providing the device with assurance that the  
1253 network that is trying to onboard it is authorized to do so can take a variety of forms, depending  
1254 on the network-layer onboarding protocol being used. For example, if the Wi-Fi Easy Connect  
1255 protocol is being used, then if an entity is in possession of the device's public key, that entity is  
1256 assumed to be authorized to onboard the device. If BRSKI is being used, the device will be  
1257 provided with a signed voucher verifying that the network that is trying to onboard the device is  
1258 authorized to do so. The voucher is signed by the MASA. Because the device manufacturer has  
1259 installed trust anchors for the MASA onto the device, the device trusts the MASA. It is also able  
1260 to verify the MASA's signature.

1261 (Note: In this document, for the sake of simplicity, we often refer to the network that is  
1262 authorized to onboard a device as the device owner's network. In reality, it may not always be  
1263 the case that the device's owner also owns the network to which the device is being onboarded.  
1264 While it is assumed that a network that owns a device is authorized to onboard it, and the  
1265 device and the onboarding network are often owned by the same entity, common ownership is

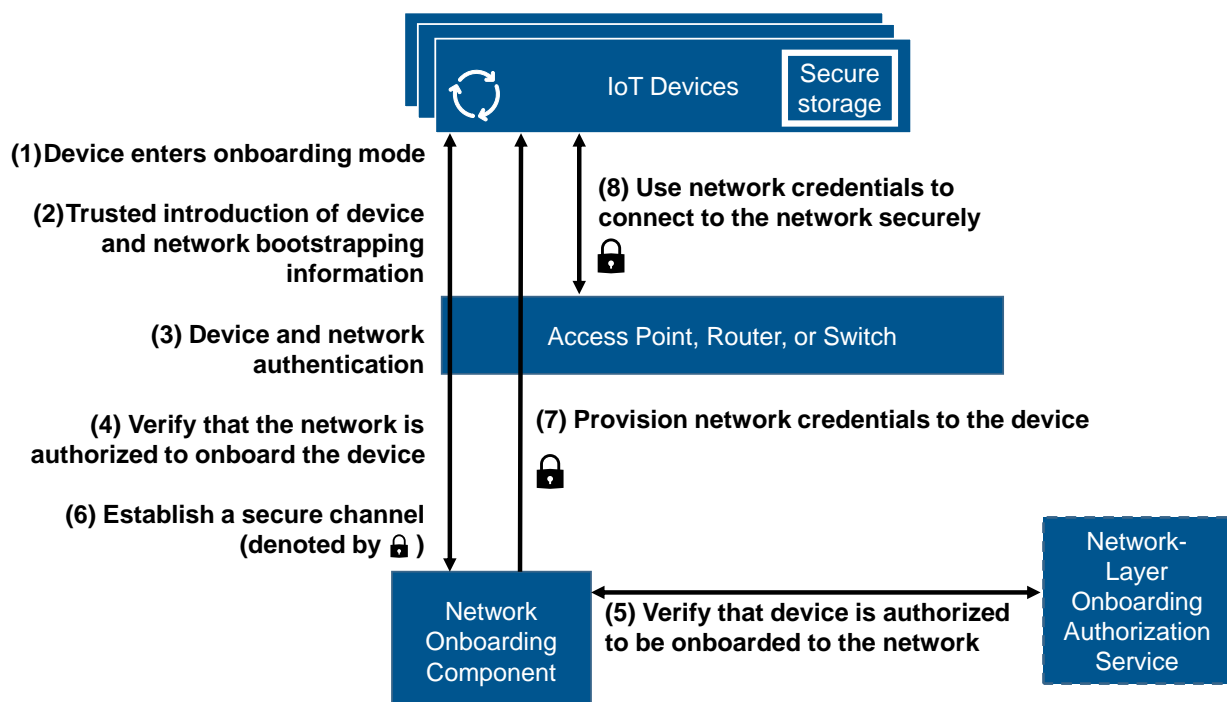

1266 not a requirement. The network that is onboarding a device does not have to be the owner of  
 1267 that device. The network owner may permit devices that it does not own to be onboarded to  
 1268 the network. In order for such a device to be onboarded, the network owner must be in  
 1269 possession of the device's bootstrapping information. By accepting the bootstrapping  
 1270 information, the network owner is implicitly authorizing the device to be onboarded to its  
 1271 network. Conversely, a device may permit itself to be onboarded to a network that is not owned  
 1272 by the device's owner. A device owner that wants to authorize a network to onboard the device  
 1273 needs to ensure that the device trusts the onboarding network. The specific mechanism for  
 1274 accomplishing this will vary according to the network-layer onboarding protocol being used.  
 1275 When the Wi-Fi Easy Connect protocol is being used, simply providing the network with the  
 1276 device's public key is sufficient to authorize the network to onboard the device. When BRSKI is  
 1277 being used, the voucher that the MASA provides to the device must authorize the network to  
 1278 onboard it.)

1279 Authentication of the network by the device may also take a variety of forms. These may range  
 1280 from simply trusting the person who is onboarding the device to onboard it to the correct  
 1281 network, to providing the IoT device with the network's public key.

### 1282 4.3 Trusted Network-Layer Onboarding Process

1283 Figure 4-4 depicts the trusted network-layer onboarding process in more detail. It shows the  
 1284 interactions that occur between the network-layer onboarding component and the IoT device to  
 1285 mutually authenticate, confirm that the device is authorized to be onboarded to the network, confirm  
 1286 that the network is authorized to onboard the device, establish a secure channel, and provision the  
 1287 device with its network credentials.

1288 **Figure 4-4 Trusted Network-Layer Onboarding Process**

1289 The numbered arrows in the diagram are intended to provide a high-level summary of the network-layer  
1290 onboarding steps. These steps are assumed to occur after any device bootstrapping information and  
1291 ownership transfer activities (as described in the previous section) that may need to be performed. The  
1292 steps of the trusted network-layer onboarding process are as follows:

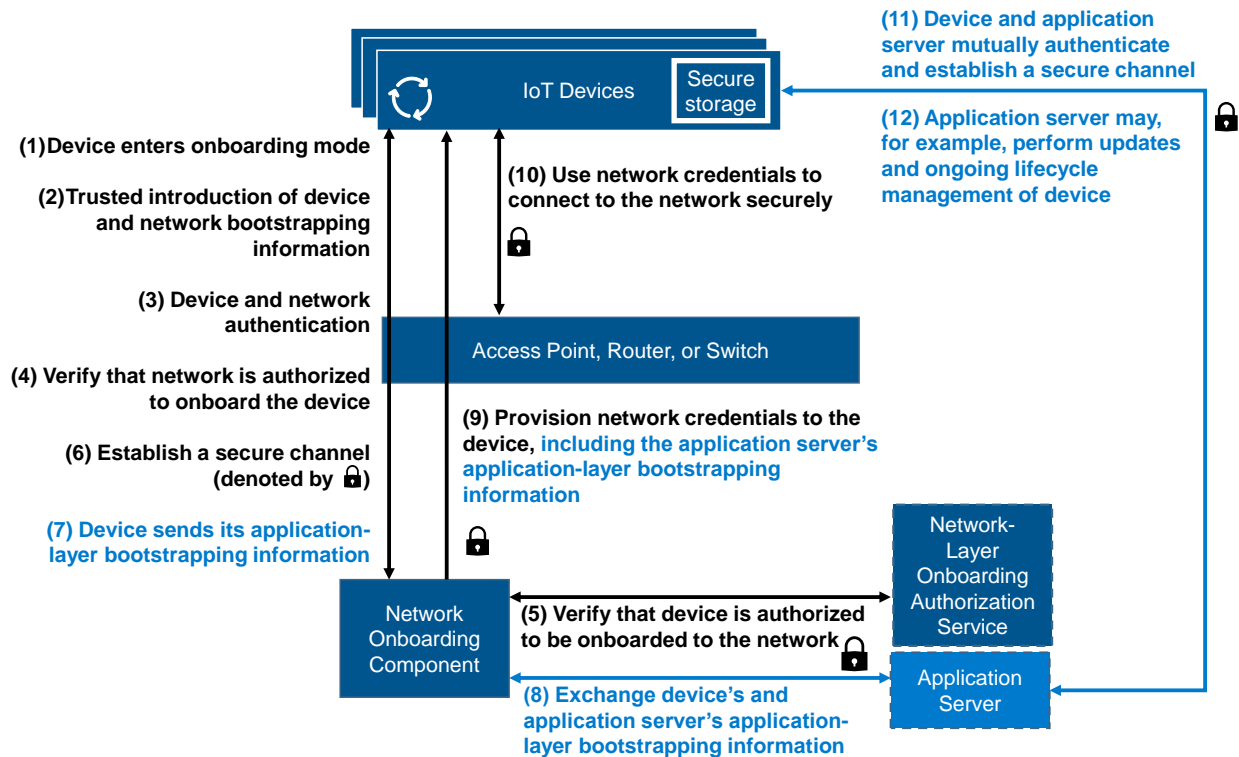

- 1293 1. The IoT device to be onboarded is placed in onboarding mode, i.e., it is put into a state such that  
1294 it is actively listening for and/or sending initial onboarding protocol messages.
- 1295 2. Any required device bootstrapping information that has not already been provided to the  
1296 network and any required network bootstrapping information that has not already been  
1297 provided to the device are introduced in a trusted manner.
- 1298 3. Using the device and network bootstrapping information that has been provided, the network  
1299 authenticates the identity of the IoT device (e.g., by ensuring that the IoT device is in possession  
1300 of the private key that corresponds with the public key for the device that was provided as part  
1301 of the device's bootstrapping information), and the IoT device authenticates the identity of the  
1302 network (e.g., by ensuring that the network is in possession of the private key that corresponds  
1303 with the public key for the network that was provided as part of the network's bootstrapping  
1304 information).
- 1305 4. The device verifies that the network is authorized to onboard it. For example, the device may  
1306 verify that it and the network are owned by the same entity, and therefore, assume that the  
1307 network is authorized to onboard it.
- 1308 5. The network onboarding component consults the network-layer onboarding authorization  
1309 service to verify that the device is authorized to be onboarded to the network. For example, the  
1310 network-layer authorization service can confirm that the device is owned by the network and is  
1311 on the list of devices authorized to be onboarded.
- 1312 6. A secure (i.e., encrypted) channel is established between the network onboarding component  
1313 and the device.
- 1314 7. The network onboarding component uses the secure channel that it has established with the  
1315 device to confidentially send the device its unique network credentials.
- 1316 8. The device uses its newly provisioned network credentials to establish secure connectivity to the  
1317 network. The access point, router, or switch validates the device's credentials in this step. The  
1318 mechanism it uses to do so varies depending on the implementation and is not depicted in  
1319 Figure 4-4.

#### 1320 4.4 Trusted Application-Layer Onboarding Process

1321 Figure 4-5 depicts the trusted application-layer onboarding process as enabled by the streamlined  
1322 application-layer onboarding mechanism. As defined in [Section 3.3.2](#), streamlined application-layer  
1323 onboarding occurs after network-layer onboarding and depends upon and is enabled by it. The figure  
1324 uses two colors. The dark-blue components are those used in the network-layer onboarding process.  
1325 They and their accompanying steps (written in black font) are identical to those found in the trusted  
1326 network-layer onboarding process diagram provided in [Figure 4-4](#). The light-blue component and its

1327 accompanying steps (written in light-blue font) depict the portion of the diagram that is specific to  
 1328 streamlined application-layer onboarding.

1329 **Figure 4-5 Trusted Streamlined Application-Layer Onboarding Process**

1330 As is the case with [Figure 4-4](#), the steps in this diagram are assumed to occur after any device ownership  
 1331 and bootstrapping information transfer activities that may need to be performed. Steps 1-6 in this figure  
 1332 are identical to Steps 1-6 in the trusted network-layer onboarding diagram of Figure 4-4, but steps 7 and  
 1333 8 are different. With the completion of steps 1-6 in Figure 4-5, a secure channel has been established  
 1334 between the IoT device and the network-layer onboarding component. However, the device does not  
 1335 get provisioned with its network-layer credentials until step 9. To support streamlined application-layer  
 1336 onboarding, additional steps are required. Steps 1-12 are as follows:

- 1337 1. The IoT device to be onboarded is placed in onboarding mode, i.e., it is put into a state such that  
 1338 it is actively listening for and/or sending initial onboarding protocol messages.
- 1339 2. Any required device bootstrapping information that has not already been provided to the  
 1340 network and any required network bootstrapping information that has not already been  
 1341 provided to the device are introduced in a trusted manner.
- 1342 3. Using the device and network bootstrapping information that has been provided, the network  
 1343 authenticates the identity of the IoT device (e.g., by ensuring that the IoT device is in possession  
 1344 of the private key that corresponds with the public key for the device that was provided as part  
 1345 of the device's bootstrapping information), and the IoT device authenticates the identity of the  
 1346 network (e.g., by ensuring that the network is in possession of the private key that corresponds

- 1347 with the public key for the network that was provided as part of the network's bootstrapping  
1348 information).
- 1349 4. The device verifies that the network is authorized to onboard it. For example, the device may  
1350 verify that it and the network are owned by the same entity, and therefore, assume that the  
1351 network is authorized to onboard it.
  - 1352 5. The network onboarding component consults the network-layer onboarding authorization  
1353 service to verify that the device is authorized to be onboarded to the network. For example, the  
1354 network-layer authorization service can confirm that the device is owned by the network and is  
1355 on the list of devices authorized to be onboarded.
  - 1356 6. A secure (i.e., encrypted) channel is established between the network onboarding component  
1357 and the device.
  - 1358 7. The device sends its application-layer bootstrapping information to the network onboarding  
1359 component. Just as the network required the trusted introduction of device network-layer  
1360 bootstrapping information in order to enable the network to authenticate the device and ensure  
1361 that the device was authorized to be network-layer onboarded, the application server requires  
1362 the trusted introduction of device application-layer bootstrapping information to enable the  
1363 application server to authenticate the device at the application layer and ensure that the device  
1364 is authorized to be application-layer onboarded. Because this application-layer bootstrapping  
1365 information is being sent over a secure channel, its integrity and confidentiality are ensured.
  - 1366 8. The network onboarding component forwards the device's application-layer bootstrapping  
1367 information to the application server. In response, the application server provides its  
1368 application-layer bootstrapping information to the network-layer onboarding component for  
1369 eventual forwarding to the IoT device. The IoT device needs the application server's  
1370 bootstrapping information to enable the device to authenticate the application server and  
1371 ensure that it is authorized to application-layer onboard the device.
  - 1372 9. The network onboarding component uses the secure channel that it has established with the IoT  
1373 device to confidentially send the device its unique network credentials. Along with these  
1374 network credentials, the network onboarding component also sends the IoT device the  
1375 application server's bootstrapping information. Because the application server's bootstrapping  
1376 information is being sent over a secure channel, its integrity and confidentiality are ensured.z
  - 1377 10. The device uses its newly provisioned network credentials to establish secure connectivity to the  
1378 network.
  - 1379 11. Using the device and application server application-layer bootstrapping information that has  
1380 already been exchanged in a trusted manner, the application server authenticates the identity  
1381 of the IoT device and the IoT device authenticates the identity of the application server. Then  
1382 they establish a secure (i.e., encrypted) channel.
  - 1383 12. The application server application layer onboards the IoT device. This application-layer  
1384 onboarding process may take a variety of forms. For example, the application server may  
1385 download an application to the device for the device to execute. It may associate the device

1386 with a trusted lifecycle management service that performs ongoing updates of the IoT device to  
 1387 patch it as needed to ensure that the device remains compliant with policy.

## 1388 4.5 Continuous Verification

1389 [Figure 4-6](#) depicts the steps that are performed to support continuous verification. The figure uses two  
 1390 colors. The light-blue component and its accompanying steps (written in light-blue font) depict the  
 1391 portion of the diagram that is specific to continuous authorization. The dark-blue components are those  
 1392 used in the network-layer onboarding process. They and their accompanying steps (written in black  
 1393 font) are identical to those found in the trusted network-layer onboarding process diagram provided in  
 1394 [Figure 4-4](#), except for step 5, *Verify that device is authorized to be onboarded to the network*.

1395 **Figure 4-6 Continuous Verification**

1396 When continuous verification is being supported, step 5 is broken into two separate steps, as shown in  
 1397 [Figure 4-6](#). Instead of the network onboarding component directly contacting the network-layer  
 1398 onboarding authorization service to see if the device is owned by the network and on the list of devices  
 1399 authorized to be onboarded (as shown in the trusted network-layer onboarding architecture depicted in  
 1400 [Figure 4-4](#)), a set of other enterprise policies may also be applied to determine if the device is authorized  
 1401 to be onboarded. The application of these policies is represented by the insertion of the Continuous  
 1402 Authorization Service (CAS) component in the middle of the exchange between the network onboarding  
 1403 component and the network-layer onboarding authorization service.

1404 For example, the CAS may have received external threat information indicating that certain device types  
 1405 have a vulnerability. If so, when the CAS receives a request from the network-layer onboarding  
 1406 component to verify that a device of this type is authorized to be onboarded to the network (Step 5a), it  
 1407 would immediately respond to the network-layer onboarding component that the device is not  
 1408 authorized to be onboarded to the network. If the CAS has not received any such threat information

1409 about the device and it checks all its policies and determines that the device should be permitted to be  
1410 onboarded, it will forward the request to the network-layer onboarding authorization service (Step 5b)  
1411 and receive a response (Step 5b) that it will forward to the network onboarding component (Step 5a).

1412 As depicted by Step 9, the CAS also continues to operate after the device connects to the network and  
1413 executes its application. The CAS performs asynchronous calls to the network router to monitor the  
1414 device on an ongoing basis, providing policy-based verification and authorization checks on the device  
1415 throughout its lifecycle.

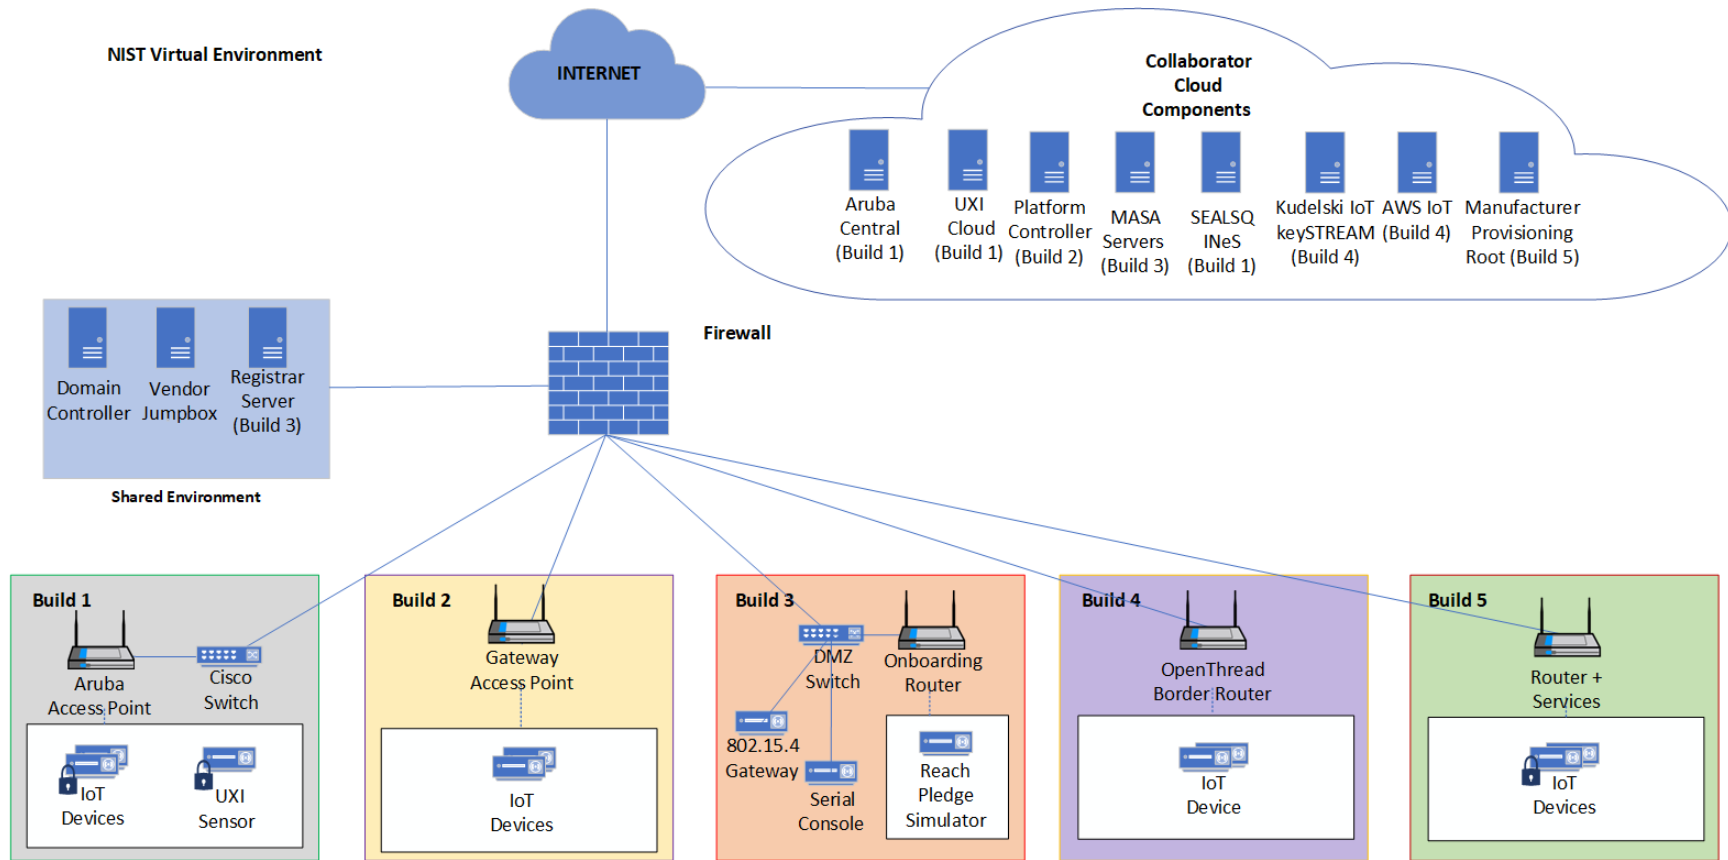

## 1416 5 Laboratory Physical Architecture

1417 [Figure 5-1](#) depicts the high-level physical architecture of the NCCoE IoT Onboarding laboratory  
1418 environment in which the five trusted IoT device network-layer onboarding project builds, and the  
1419 factory provisioning builds are being implemented. The NCCoE provides virtual machine (VM) resources  
1420 and physical infrastructure for the IoT Onboarding lab. As depicted, the NCCoE IoT Onboarding  
1421 laboratory hosts collaborator hardware and software for the builds. The NCCoE also provides  
1422 connectivity from the IoT Onboarding lab to the NIST Data Center, which provides connectivity to the  
1423 internet and public IP spaces (both IPv4 and IPv6). Access to and from the NCCoE network is protected  
1424 by a firewall.

1425 Access to and from the IoT Onboarding lab is protected by a pfSense firewall, represented by the brick  
1426 box icon in [Figure 5-1](#). This firewall has both IPv4 and IPv6 (dual stack) configured. The IoT Onboarding  
1427 lab network infrastructure includes a shared virtual environment that houses a domain controller and a  
1428 vendor jumpbox. These components are used across builds where applicable. It also contains five  
1429 independent virtual LANs, each of which houses a different trusted network-layer onboarding build.

1430 The IoT Onboarding laboratory network has access to cloud components and services provided by the  
1431 collaborators, all of which are available via the internet. These components and services include Aruba  
1432 Central and the UXI Cloud (Build 1), SEALSQ INeS (Build 1), Platform Controller (Build 2), a MASA server  
1433 (Build 3), Kudelski IoT keySTREAM application-layer onboarding service and AWS IoT (Build 4), and a  
1434 Manufacturer Provisioning Root (Build 5).

1435 Figure 5-1 NCCoE IoT Onboarding Laboratory Physical Architecture

1436 All five network-layer onboarding laboratory environments, as depicted in the diagram, have been  
1437 installed:

- 1438       ▪ The Build 1 (i.e., the Wi-Fi Easy Connect, Aruba/HPE build) network infrastructure within the  
1439       NCCoE lab consists of two components: the Aruba Access Point and the Cisco Switch. Build 1  
1440       also requires support from Aruba Central for network-layer onboarding and the UXI Cloud for  
1441       application-layer onboarding. These components are in the cloud and accessed via the internet.  
1442       The IoT devices that are onboarded using Build 1 include the UXI Sensor and the Raspberry Pi.
- 1443       ▪ The Build 2 (i.e., the Wi-Fi Easy Connect, CableLabs, OCF build) network infrastructure within the  
1444       NCCoE lab consists of a single component: the Gateway Access Point. Build 2 requires support  
1445       from the Platform Controller, which also hosts the IoTivity Cloud Service. The IoT devices that  
1446       are onboarded using Build 2 include three Raspberry Pis.
- 1447       ▪ The Build 3 (i.e., the BRSKI, Sandelman Software Works build) network infrastructure  
1448       components within the NCCoE lab include a Wi-Fi capable home router (including Join Proxy), a  
1449       DMZ switch (for management), and an ESP32A Xtensa board acting as a Wi-Fi IoT device, as well  
1450       as an nRF52840 board acting as an IEEE 802.15.4 device. A management system on a  
1451       BeagleBone Green serves as a serial console. A registrar server has been deployed as a virtual  
1452       appliance on the NCCoE private cloud system. Build 3 also requires support from a MASA server  
1453       which is accessed via the internet. In addition, a Raspberry Pi 3 provides an ethernet/802.15.4  
1454       gateway, as well as a test platform.
- 1455       ▪ The Build 4 (i.e., the Thread, Silicon Labs, Kudelski IoT build) network infrastructure components  
1456       within the NCCoE lab include an Open Thread Border Router, which is implemented using a  
1457       Raspberry Pi, and a Silicon Labs Gecko Wireless Starter Kit, which acts as an 802.15.4 antenna.  
1458       Build 4 also requires support from the Kudelski IoT keySTREAM service, which is in the cloud and  
1459       accessed via the internet. The IoT device that is onboarded in Build 4 is the Silicon Labs Dev Kit  
1460       (BRD2601A) with an EFR32MG24 System-on-Chip (SoC). The application service to which it  
1461       onboards is AWS IoT.
- 1462       ▪ The Build 5 (i.e., the BRSKI over Wi-Fi, NquiringMinds build) includes 2 Raspberry Pi 4Bs running  
1463       a Linux operating system. One Raspberry Pi acts as the pledge (or IoT Device) with an Infineon  
1464       TPM connected. The other acts as the router, registrar and MASA all in one device. This build  
1465       uses the open source TrustNetZ distribution, from which the entire build can be replicated  
1466       easily. The TrustNetZ distribution includes source code for the IoT device, the router, the access  
1467       point, the network onboarding component, the policy engine, the manufacturer services, the  
1468       registrar and a demo application server. TrustNetZ makes use of NquiringMinds tdx Volt to issue  
1469       and validate verifiable credentials.
- 1470       ▪ The BRSKI factory provisioning build is deployed in the Build 5 environment. The IoT device in  
1471       this build is a Raspberry Pi equipped with an Infineon Optiga SLB 9670 TPM 2.0, which gets  
1472       provisioned with birth credentials (i.e., a public/private key pair and an IDevID). The BRSKI  
1473       factory provisioning build also uses an external certificate authority hosted on the premises of  
1474       NquiringMinds to provide the device certificate signing service.
- 1475       ▪ The Wi-Fi Easy Connect factory provisioning build is deployed in the Build 1 environment. Its IoT  
1476       devices are Raspberry Pis equipped with a SEALSQ VaultIC Secure Element, which gets  
1477       provisioned with a DPP URI. The Secure Element can also be provisioned with an IDevID  
1478       certificate signed by the SEALSQ INeS certification authority, which is independent of the DPP  
1479       URI. Code for performing the factory provisioning is stored on an SD card.

1480 Information regarding the physical architecture of all builds, their related collaborators' cloud  
 1481 components, and the shared environment, as well as the baseline software running on these physical  
 1482 architectures, are described in the subsections below. Table 5-1 summarizes the builds that were  
 1483 implemented and provides links to the appendices where each is described in detail.

1484 **Table 5-1 Build 1 Products and Technologies**

Build	Network-Layer Protocols	Build Champions	Link to Details
<b>Onboarding Builds</b>			
Build 1	Wi-Fi Easy Connect	Aruba/HPE	<a href="#">Appendix C</a>
Build 2	Wi-Fi Easy Connect	CableLabs and OCF	<a href="#">Appendix D</a>
Build 3	BRSKI	Sandelman Software Works	<a href="#">Appendix E</a>
Build 4	Thread	Silicon Labs and Kudelski IoT	<a href="#">Appendix F</a>
Build 5	BRSKI over Wi-Fi	NquiringMinds	<a href="#">Appendix G</a>
<b>Factory Provisioning Builds</b>			
BRSKI with Build 5	BRSKI over WIFI	SEALSQ and NquiringMinds	<a href="#">Appendix H.3</a>
Wi-Fi Easy Connect with Build 1	Wi-Fi Easy Connect	SEALSQ and Aruba/HPE	<a href="#">Appendix H.4</a>

## 1485 **5.1 Shared Environment**

1486 The NCCoE IoT Onboarding laboratory contains a shared environment to host several baseline services  
 1487 in support of the builds. These baseline services supported configuration and integration work in each of  
 1488 the builds and allowed collaborators to work together throughout the build process. This shared  
 1489 environment is contained in its own network segment, with access to/from the rest of the lab  
 1490 environment closely controlled. In addition, each of the systems in the shared environment is hardened  
 1491 with baseline configurations.

### 1492 **5.1.1 Domain Controller**

1493 The Domain Controller provides Active Directory and Domain Name System (DNS) services supporting  
 1494 network access and access control in the lab. It runs on Windows Server 2019.

### 1495 **5.1.2 Jumpbox**

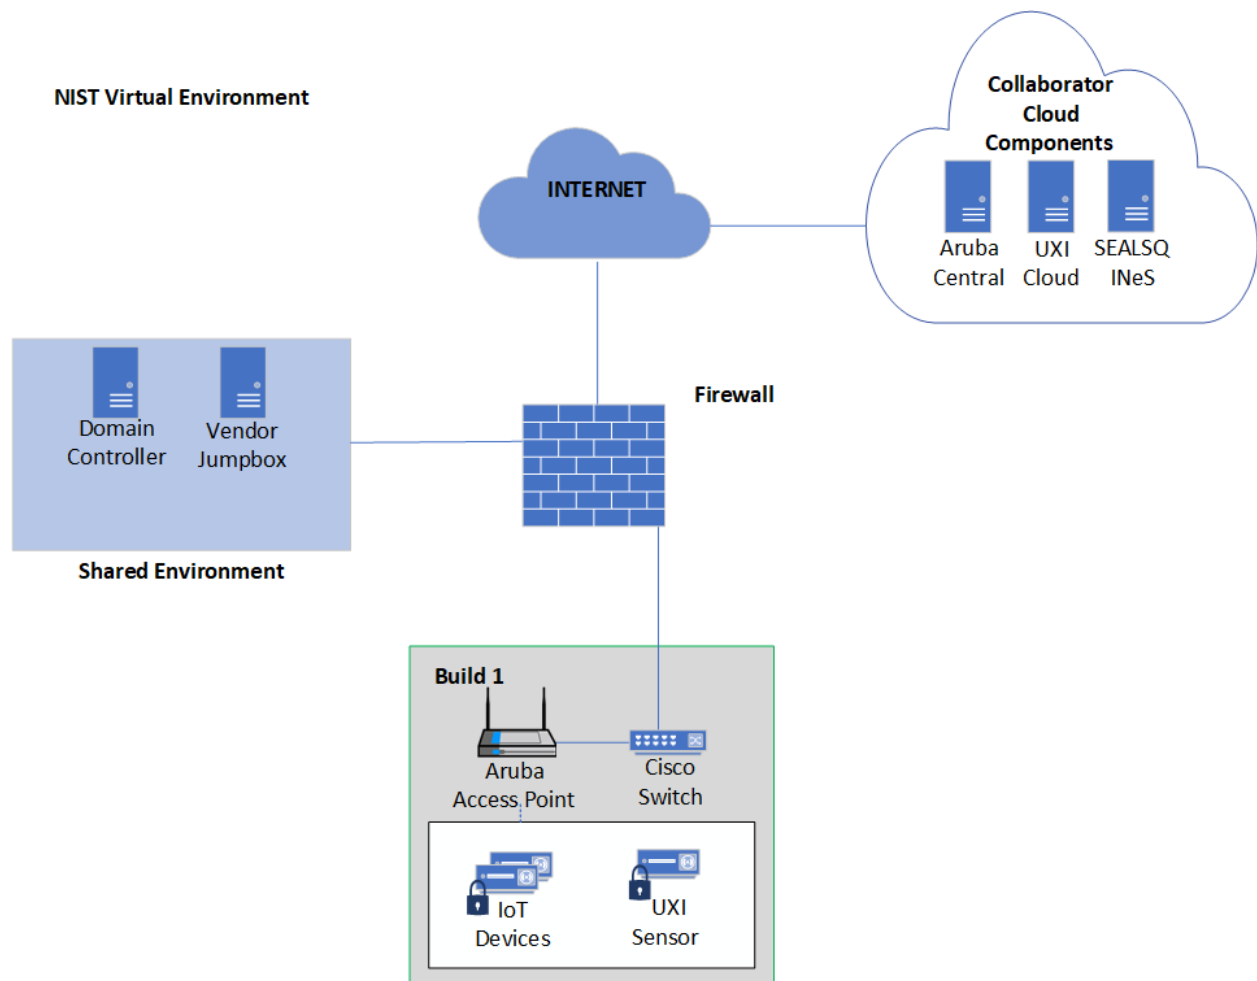

1496 The jumpbox provides secure remote access and management to authorized collaborators on each of  
 1497 the builds. It runs on Windows Server 2019.

## 1498 5.2 Build 1 (Wi-Fi Easy Connect, Aruba/HPE) Physical Architecture

1499 [Figure 5-2](#) is a view of the high-level physical architecture of Build 1 in the NCCoE IoT Onboarding  
1500 laboratory. The build components include an Aruba Wireless Access Point, Aruba Central, UXI Cloud, a  
1501 Cisco Catalyst switch, a SEALSQ INeS CMS CA, and the IoT devices to be onboarded, which include both a  
1502 Raspberry Pi and a UXI sensor. Most of these components are described in [Section 3.4.1](#) and [Section](#)  
1503 [3.4.3](#).

- 1504       ▪ The Aruba Access Point acts as the DPP Configurator and relies on the Aruba Central cloud  
1505       service for authentication and management purposes.
- 1506       ▪ Aruba Central ties together the IoT Operations, Client Insights, and Cloud Auth services to  
1507       support the network-layer onboarding operations of the build. It also provides an API to support  
1508       the device ownership and bootstrapping information transfer process.
- 1509       ▪ The Cisco Catalyst Switch provides Power-over-Ethernet and network connectivity to the Aruba  
1510       Access Point.
- 1511       ▪ The UXI Sensor acts as an IoT device and onboards to the network via Wi-Fi Easy Connect. After  
1512       network-layer onboarding, it performs independent (see [Section 3.3.2](#)) application-layer  
1513       onboarding. Once it has application-layer onboarded and is operational on the network, it does  
1514       passive and active monitoring of applications and services and will report outages, disruptions,  
1515       and quality of service issues.
- 1516       ▪ UXI Cloud is an HPE cloud service that the UXI sensor contacts as part of the application-layer  
1517       onboarding process. The UXI sensor downloads a customer-specific configuration from the UXI  
1518       Cloud so that the UXI sensor can learn about the customer networks and services it needs to  
1519       monitor.
- 1520       ▪ The Raspberry Pi acts as an IoT device and onboards to the network via Wi-Fi Easy Connect.
- 1521       ▪ SEALSQ Certificate Authority has been integrated with Build 1 to sign network credentials that  
1522       are issued to IoT devices.

1523 Figure 5-2 Physical Architecture of Build 1

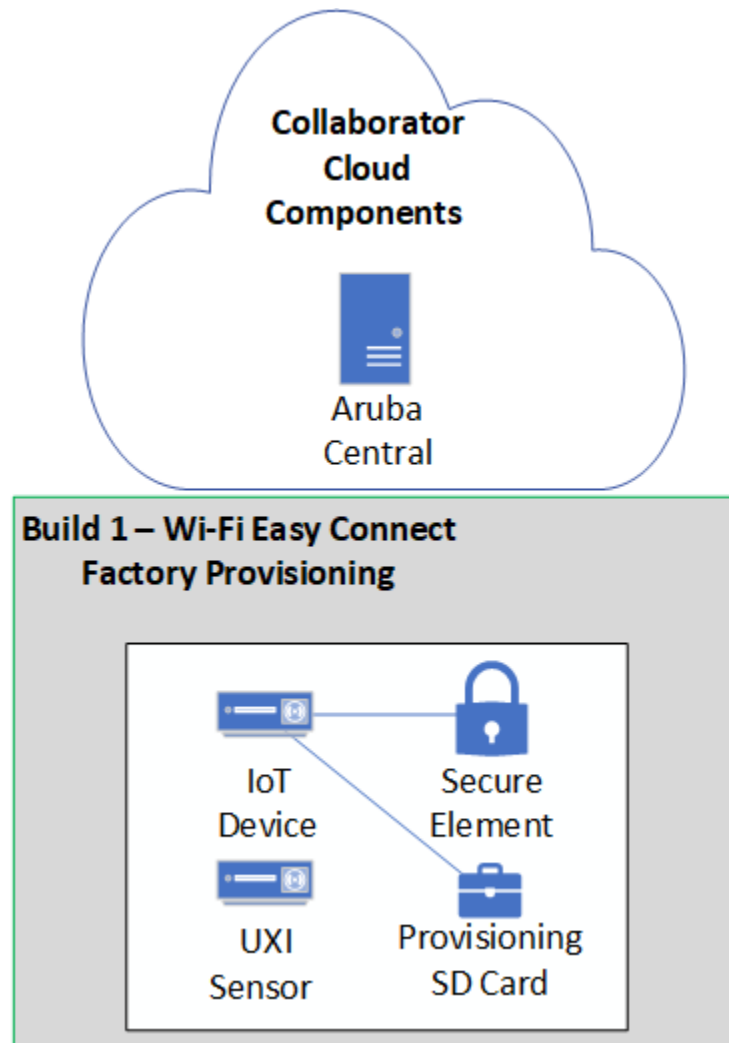

### 1524 5.2.1 Wi-Fi Easy Connect Factory Provisioning Build Physical Architecture

1525 [Figure 5-3](#) is a view of the high-level physical architecture of the Wi-Fi Easy Connect Factory Provisioning  
 1526 Build in the NCCoE IoT Onboarding laboratory. The build components include the IoT device, an SD card  
 1527 with factory provisioning code on it, and a Secure Element. See [Appendix H.4](#) for additional details on  
 1528 the Wi-Fi Easy Connect Factory Provisioning Build.

- 1529     ▪ A UXI sensor.
- 1530     ▪ The IoT Device is a Raspberry Pi.
- 1531     ▪ The Secure Element is a SEALSQ VaultIC Secure Element and is interfaced with the Raspberry Pi.  
 1532 The Secure Element both generates and stores the key material necessary to support the DPP  
 1533 URI during the Factory Provisioning Process.
- 1534     ▪ An SD card with factory provisioning code.
- 1535     ▪ Aruba Central provides an API to ingest the DPP URI in support of the device ownership and  
 1536 bootstrapping information transfer process.

1537 Figure 5-3 Physical Architecture of Wi-Fi Easy Connect Factory Provisioning Build

### 1538 5.3 Build 2 (Wi-Fi Easy Connect, CableLabs, OCF) Physical Architecture

1539 Figure 5-3 is a view of the high-level physical architecture of Build 2 in the NCCoE IoT Onboarding  
 1540 laboratory. The Build 2 components include the Gateway Access Point, three IoT devices, and the  
 1541 Platform Controller, which hosts the application-layer IoTivity service.

- 1542     ▪ The Gateway Access Point acts as the Custom Connectivity Gateway Agent described in [Section](#)  
 1543 [3.4.2.2](#) and controls all network-layer onboarding activity within the network. It also hosts OCF  
 1544 IoTivity functions, such as the OCF OBT and the OCF Diplomat.
- 1545     ▪ The Platform Controller described in [Section 3.4.2.1](#) provides management capabilities for the  
 1546 Custom Connectivity Gateway Agent. It also hosts the application-layer IoTivity service for the  
 1547 IoT devices as described in [Section 3.4.8.1](#).
- 1548     ▪ The IoT devices serve as reference clients, as described in [Section 3.4.2.3](#). They run OCF  
 1549 reference implementations. The IoT devices are onboarded to the network and complete both  
 1550 application-layer and network-layer onboarding.

1551 **Figure 5-4 Physical Architecture of Build 2**

## 1552 **5.4 Build 3 (BRSKI, Sandelman Software Works) Physical Architecture**

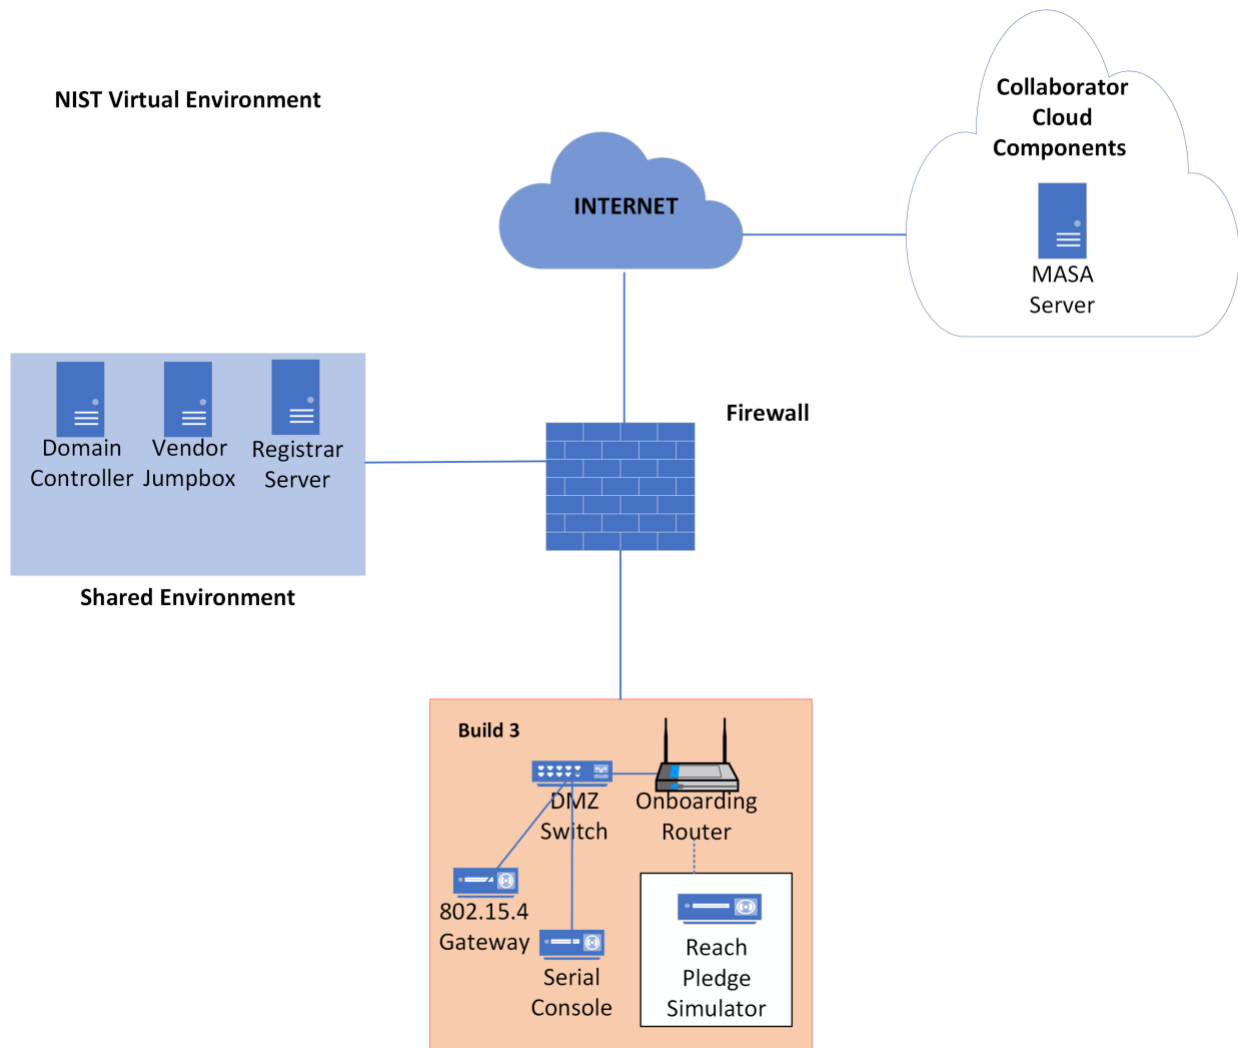

1553 Figure 5-4 is a view of the high-level physical architecture of Build 3 in the NCCoE IoT Onboarding  
 1554 laboratory. The Build 3 components include the onboarding router, a Registrar Server, a MASA server, a  
 1555 DMZ switch, IoT devices, a serial console, and an 802.15.4 gateway.

- 1556     ▪ The onboarding router is a Turris MOX router running OpenWRT. The onboarding router  
 1557     quarantines the IoT devices until they complete the BRSKI onboarding process.
- 1558     ▪ The owner's Registrar Server hosts the Minerva Fountain Join Registrar Coordinator application  
 1559     running in a virtual machine. The Registrar Server determines whether or not a device meets the  
 1560     criteria to join the network.
- 1561     ▪ The MASA server for this build is a Minerva Highway MASA server as outlined in [Section 3.4.9.1](#).  
 1562     The role of the MASA server is to receive the voucher-request from the Registrar Server and  
 1563     confirm that the Registrar Server has the right to own the device.

- 1564      ■ The DMZ switch is a basic Netgear switch that segments the build from the rest of the lab.
- 1565      ■ The IoT devices include an ESP32 Xtensa device with Wi-Fi that will be tested with FreeRTOS and
- 1566      RIOT-OS, a Raspberry Pi 3 running Raspbian 11, and an nRF52840 with an 802.15.4 radio that is
- 1567      running RIOT-OS. The IoT devices are currently not used in the build but will serve as clients to
- 1568      be onboarded onto the network in a future implementation of the build.
- 1569      ■ The Sandelman Software Works Reach Pledge Simulator is the device that is onboarded to the
- 1570      network in the current build.
- 1571      ■ The serial console is a BeagleBone Green with an attached USB hub. The serial console is used to
- 1572      access the IoT devices for diagnostic purposes. It also provides power and power control for
- 1573      USB-powered devices.
- 1574      ■ The 802.15.4 gateway is integrated into the Raspberry Pi 3 via an OpenMote daughter card. This
- 1575      gateway will serve to onboard one of the IoT devices in a future implementation of this build.

1576      **Figure 5-5 Physical Architecture of Build 3**

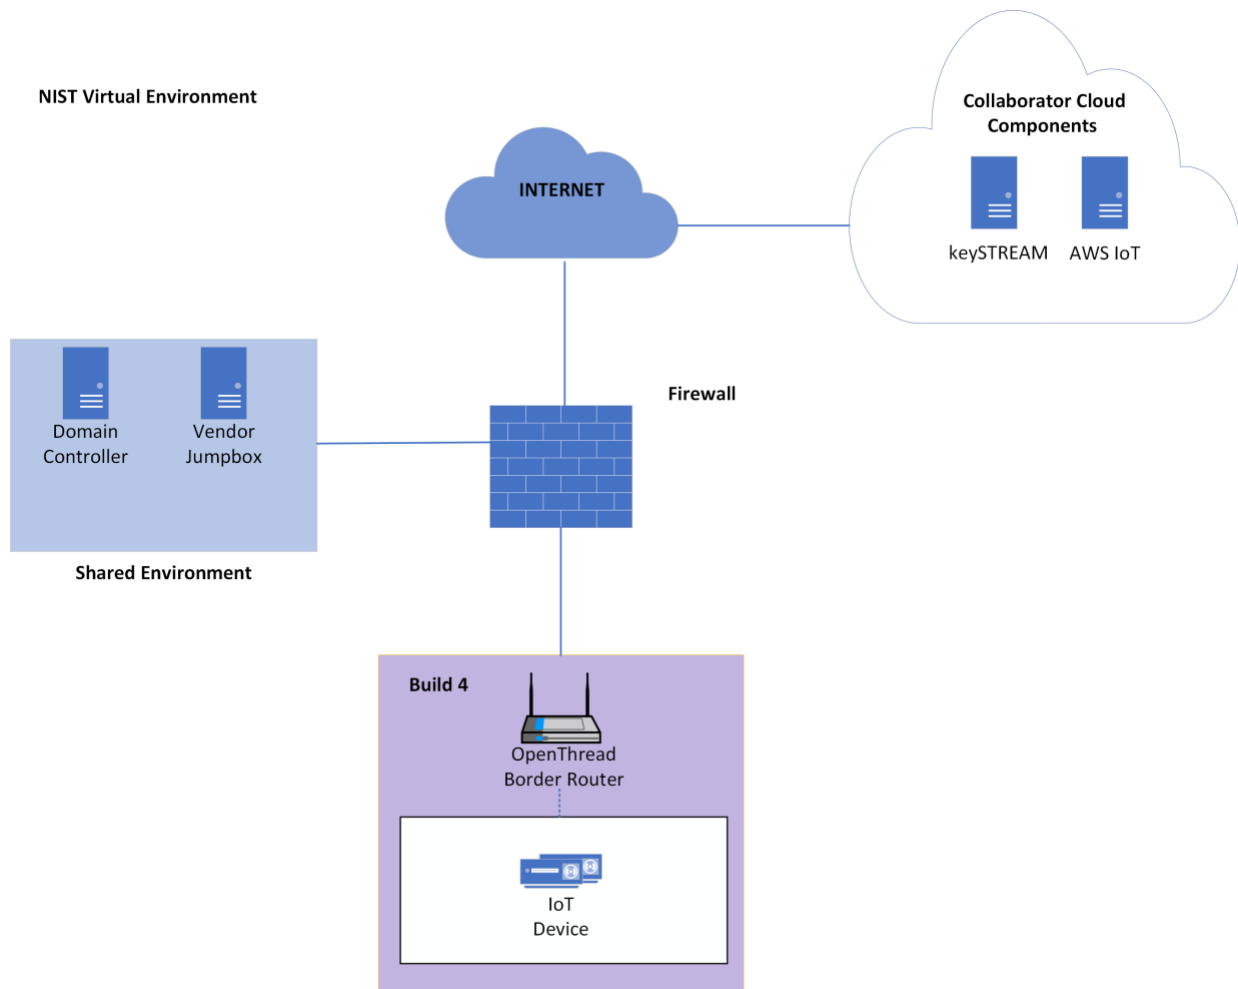

## 1577 5.5 Build 4 (Thread, Silicon Labs, Kudelski IoT) Physical Architecture

1578 Figure 5-6 is a view of the high-level physical architecture of Build 4 in the NCCoE IoT Onboarding  
1579 laboratory. The Build 4 components include a keySTREAM server, an AWS IoT server, an OpenThread  
1580 Border Router, and a Thread IoT device.

- 1581     ▪ The keySTREAM server described in [Section 3.4.5.1](#) is the application layer onboarding service  
1582     provided by Kudelski IoT. The IoT device will authenticate to keySTREAM using a Silicon Labs  
1583     chip birth certificate and private key and leveraging Silicon Labs' Secure Engine in the  
1584     EFR32MG24 chipset ("Secure Vault(TM) High" which is security certified Platform Security  
1585     Architecture (PSA)/Security Evaluation Standard for IoT Platforms (SESIP) Level 3 to protect that  
1586     birth identity with Secure Boot, Secure Debug, and physically unclonable function (PUF)  
1587     wrapped key storage and hardware tamper protection).
- 1588     ▪ The AWS IoT server provides the MQTT test client for the trusted application-layer onboarding.  
1589     The Proof of Possession Certificate is provisioned for the device using a registration code from  
1590     the AWS server.
- 1591     ▪ The OpenThread Border Router is run on a Raspberry Pi 3B and serves as the Thread  
1592     Commissioner and Leader. It communicates with the IoT device by means of a Silicon Labs  
1593     Gecko Wireless Devkit which serves as the 802.15.4 antenna for the build.
- 1594     ▪ The IoT Device in this build is a Silicon Labs Thunderboard (BRD2601A) containing the  
1595     EFR32MG24Bx 15.4 SoC with Secure Vault (TM) High running the Thread protocol. It serves as  
1596     the child node on the Thread network and is onboarded onto AWS IoT Core using credentials  
1597     provisioned from the Kudelski keySTREAM service.

1598 Figure 5-6 Physical Architecture of Build 4

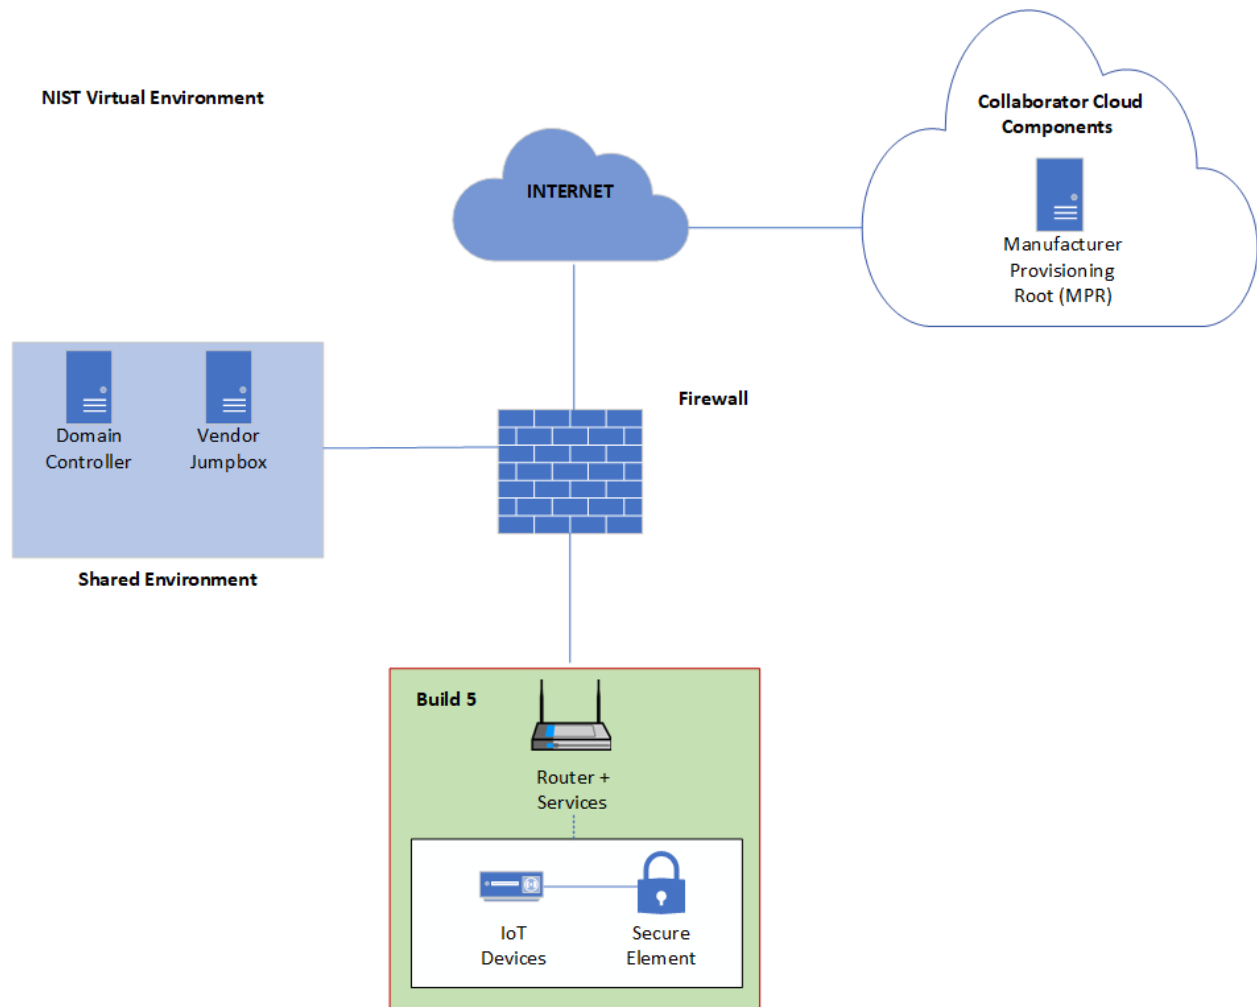

## 1599 5.6 Build 5 (BRSKI, NquiringMinds) Physical Architecture

1600 Figure 5-6 is a view of the high-level physical architecture of Build 5 in the NCCoE IoT Onboarding  
 1601 laboratory. The Build 5 components include a MASA, Registrar, Router Access Point, an IoT Device, and a  
 1602 Secure Element:

- 1603     ▪ A Raspberry Pi 4B serves as the MASA, Registrar and Router Access Point for the local network.  
 1604     The role of the MASA is to receive the voucher-request from the Registrar and confirm that the  
 1605     Registrar has the right to own the device. The registrar self-signs credentials, namely the Local  
 1606     Device Identifier (LDevID), issued to the IoT devices. The pledge (IoT device) gets its IDDevID  
 1607     certificate for device identity from the Manufacturer Provisioning Root (MPR) server during the  
 1608     factory provisioning process, it can be assumed to be present on the device at the point of  
 1609     onboarding. The Registrar determines whether or not a device meets the criteria to join the  
 1610     network. The router access point runs an open and closed BRSKI network, the closed BRSKI  
 1611     network may only be accessed through secure onboarding, which is performed via the open  
 1612     network. The registrar leverages a local tdx Volt instance to sign and verify verifiable credentials.
- 1613     ▪ Raspberry Pi 4Bs act as IoT Devices (pledges) for this build.

- 1614       ▪ The Secure Element is an Infineon Optiga SLB 9670 TPM 2.0 Secure Element, and both generates  
 1615 and stores the key material necessary to support the IDevID certificate during the Factory  
 1616 Provisioning Process, as well as the onboarding process to request the voucher from the MASA  
 1617 via the registrar and the request to the registrar to sign the LDevID. The system can also be  
 1618 configured to use a SEALSQ VaultIC408 secure element. See [Appendix H.3](#) for additional details  
 1619 on the BRSKI factory provisioning builds.

1620 **Figure 5-7 Physical Architecture of Build 5**

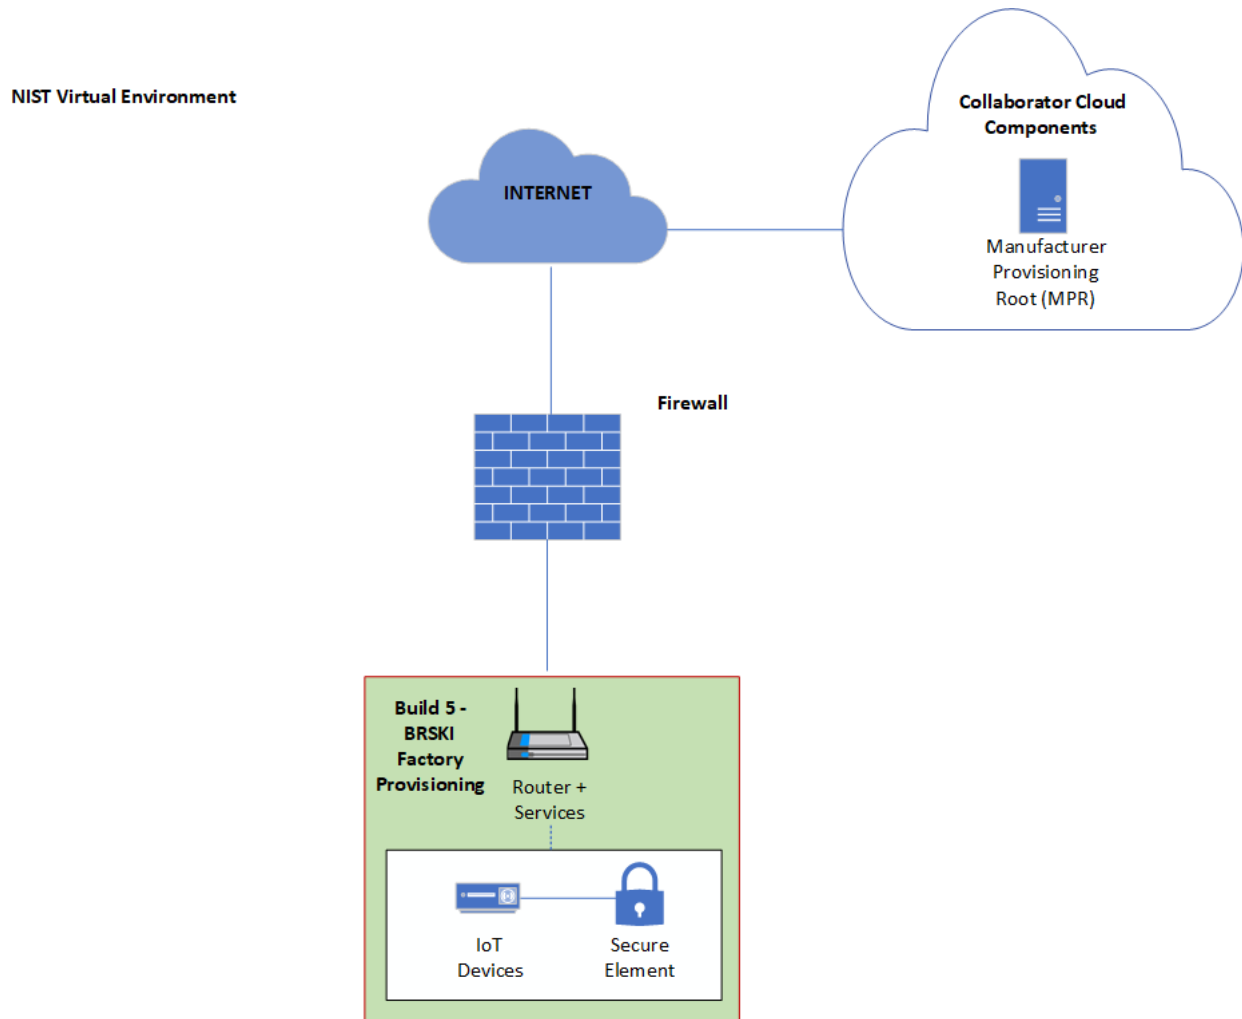

### 1621 5.6.1 BRSKI Factory Provisioning Build Physical Architecture

1622 Figure 5-8 is a view of the high-level physical architecture of the BRSKI Factory Provisioning Build in the  
 1623 NCCoE IoT Onboarding laboratory. This build uses the same IoT device as Build 5: a Raspberry Pi  
 1624 integrated with an Infineon Optiga SLB 9670 TPM 2.0 Secure Element. The factory provisioning code is  
 1625 hosted on an SD card. When a provisioning event is triggered the IoT device will attempt a connection to  
 1626 a Manufacturer Provisioning Root (MPR) server that sits in the cloud and acts as the certification  
 1627 authority. It signs the IDevID (X.509) certificate, which is then passed back to the IoT device for  
 1628 installation. As in Build 5, the Router + Services hosts a MASA, which is given device identity information

1629 in order to verify voucher requests during the BRKSI process. See [Appendix H.3](#) for additional details on  
 1630 the BRSKI factory provisioning builds.

1631 **Figure 5-8 Physical Architecture of BRSKI Factory Provisioning Build**

## 1632 6 General Findings

### 1633 6.1 Wi-Fi Easy Connect

1634 The Wi-Fi Easy Connect solution that was demonstrated in Build 1 and Build 2 supports trusted network-  
 1635 layer onboarding in a manner that is secure, efficient, and flexible enough to meet the needs of various  
 1636 use cases. It is simple enough to be used by consumers, who typically do not have specialized technical  
 1637 knowledge. In addition, to meet the needs of enterprises, it may be used to onboard a large number of  
 1638 devices quickly. Builds 1 and 2 are implementations of this protocol, and they are interoperable: IoT  
 1639 devices that were provisioned for use with Build 1 were able to be onboarded onto the network using  
 1640 Build 2, and IoT devices that were provisioned for use with Build 2 were able to be onboarded onto the  
 1641 network using Build 1.

### 1642 6.1.1 Mutual Authentication

1643 Although DPP is designed to support authentication of the network by the IoT device as well as  
1644 authentication of the device by the network, the Wi-Fi Easy Connect solutions that were demonstrated  
1645 in builds 1 and 2 do not demonstrate mutual authentication at the network layer. They only support  
1646 authentication of the device. In order to authenticate the network, the device needs to be provided with  
1647 the DPP URI for the network configurator, which means that the device has to have a functional user  
1648 interface so that the DPP URI can be input into it. The devices being used in builds 1 and 2 do not have  
1649 user interfaces.

### 1650 6.1.2 Mutual Authorization

1651 When using DPP, device authorization is based on possession of the device's DPP URI. When the device  
1652 is acquired, its DPP URI is provided to the device owner. A trusted administrator of the owner's network  
1653 is assumed to approve addition of the device's DPP URI to the database or cloud service where the DPP  
1654 URIs of authorized devices are stored. During the onboarding process, the fact that the owning network  
1655 is in possession of the device's DPP URI indicates to the network that the device is authorized to join it.

1656 DPP supports network authorization using the Resurrecting Duckling security model [13]. Although the  
1657 device cannot cryptographically verify that the network is authorized to onboard it, the fact that the  
1658 network possesses the device's public key is understood by the device to implicitly authorize the  
1659 network to onboard the device. The assumption is that an unauthorized network would not have  
1660 possession of the device and so would not be able to obtain the device's public key. While this assurance  
1661 of authorization is not cryptographic, it does provide some level of assurance that the "wrong" network  
1662 won't onboard it.

### 1663 6.1.3 Secure Storage

1664 The UXI sensor used in Build 1 has a TPM where the device's birth credential and private key are stored,  
1665 providing a secure root of trust. However, the lack of secure storage on some of the other IoT devices  
1666 (e.g., the Raspberry Pis) used to demonstrate onboarding in Build 2 is a current weakness. Ensuring that  
1667 the confidentiality of a device's birth, network, and other credentials is protected while stored on the  
1668 device is an essential aspect of ensuring the security of the network-layer onboarding process, the  
1669 device, and the network itself. To fully demonstrate trusted network-layer onboarding, devices with  
1670 secure storage should be used in the future whenever possible.

## 1671 6.2 BRSKI

1672 The BRSKI solution that is demonstrated in Build 3 supports trusted network-layer onboarding in a  
1673 manner that is secure, efficient, and able to meet the needs of enterprises. It may be used to onboard a  
1674 large number of devices quickly onto a wired network. This BRSKI build is based on IETF RFC 8995 [7].  
1675 The build has a reliance on the manufacturer to provision keys for the onboarding device and has a  
1676 reliance on a cloud-based service for the MASA server. The BRSKI solution that is demonstrated in Build  
1677 5 provides similar trusted functionality for onboarding devices onto a Wi-Fi network. This BRSKI build is  
1678 based on an IETF individual draft describing how to run BRSKI over IEEE 802.11 [10].

### 1679 6.2.1 Reliance on the Device Manufacturer

1680 Organizations implementing BRSKI (whether wired or over Wi-Fi) should be aware of the reliance that  
1681 they will have on the IoT device manufacturer in properly and securely provisioning their devices. If keys  
1682 become compromised, attackers may be able to onboard their own devices to the network, revoke  
1683 certificates to prevent legitimate devices from being onboarded, or onboard devices belonging to others  
1684 onto the attacker's network using the attacker's MASA. These concerns are addressed in depth in RFC  
1685 8995 section 11.6. If a device manufacturer goes out of business or otherwise shuts down their MASA  
1686 servers, the onboarding services for their devices will no longer function.

1687 During operation, onboarding services may become temporarily unavailable for a number of reasons. In  
1688 the case of a DoS attack on the MASA, server maintenance, or other outage on the part of the  
1689 manufacturer, an organization will not be able to access the MASA. These concerns are addressed in  
1690 depth in RFC 8995 section 11.1.

### 1691 6.2.2 Mutual Authentication

1692 BRSKI supports authentication of the IoT device by the network as well as authentication of the network  
1693 by the IoT device. The Registrar authenticates the device when it receives the IDevID from the device.  
1694 The MASA confirms that the Registrar is the legitimate owner or authorized onboarder of the device and  
1695 issues a voucher. The device is able to authenticate the network using the voucher that it receives back  
1696 from the MASA. This process is explained in depth in RFC 8995 section 11.5.

### 1697 6.2.3 Mutual Authorization

1698 BRSKI authorization for the IoT device is done via the voucher that is returned to the Registrar from the  
1699 MASA. The voucher states which network the IoT device is authorized to join. The Registrar determines  
1700 the level of access the IoT device has to the network.

### 1701 6.2.4 Secure Storage

1702 Build 5 uses a Secure Element attached to the IoT devices (e.g., Raspberry Pi devices) to store the IDevID  
1703 after it is generated during the factory provisioning process (see [Appendix H.3](#) for more details),  
1704 however the LDevID is not stored on the Secure Element after network-layer onboarding is completed.  
1705 The lack of secure storage on the IoT devices (e.g., the Raspberry Pi devices) used to demonstrate  
1706 onboarding in Build 3 is a current weakness. Ensuring that the confidentiality of a device's birth,  
1707 network, and other credentials is protected while stored on the device is an essential aspect of ensuring  
1708 the security of the network-layer onboarding process, the device, and the network itself. To fully  
1709 demonstrate trusted network-layer onboarding, devices with secure storage should be used in the  
1710 future whenever possible.

## 1711 6.3 Thread

1712 We do not have any findings with respect to trusted network-layer onboarding using the Thread  
1713 commissioning protocol. Build 4 demonstrated the connection of an IoT device to a Thread network, but  
1714 not trusted onboarding of the Thread network credentials to the device. In Build 4, a passphrase is  
1715 generated on the IoT device and then a person is required to enter this passphrase into the OpenThread

1716 Border Router’s (OTBR) web interface. This passphrase serves as a pre-shared key that the device uses  
1717 to join the Thread network. Due to the fact that a person must be privy to this passphrase in order to  
1718 provide it to the OTBR, this network-layer onboarding process is not considered to be trusted, according  
1719 to the definition of trusted network-layer onboarding that we provided in [Section 1.2](#).

1720 After connecting to the Thread network using the passphrase, the Build 4 device was successfully able to  
1721 gain access to the public IP network via a border router. This enabled the IoT device that was  
1722 communicating using the Thread wireless protocol to communicate with cloud services and use them to  
1723 successfully perform trusted application-layer onboarding to the AWS IoT Core.

## 1724 6.4 Application-Layer Onboarding

1725 We successfully demonstrated both:

- 1726     ▪ streamlined application-layer onboarding (to the OCF security domain in Build 2) and
- 1727     ▪ independent application-layer onboarding (to the UXI cloud in Build 1 and to the AWS IoT Core  
1728         using the Kudelski keySTREAM service in Build 4).

### 1729 6.4.1 Independent Application-Layer Onboarding

1730 Support for independent application-layer onboarding requires the device manufacturer to pre-  
1731 provision the device with software to support application-layer onboarding to the specific application  
1732 service (e.g., the UXI cloud or the AWS IoT Core) desired. The Kudelski keySTREAM service supports the  
1733 application-layer onboarding provided in Build 4. KeySTREAM is a device security management service  
1734 that runs as a SaaS platform on the Amazon cloud. Build 4 relies on an integration that has been  
1735 performed between Silicon Labs and Kudelski keySTREAM. KeySTREAM has integrated software libraries  
1736 with the Silicon Lab EFR32MG24 (MG24) IoT device’s secure vault to enable the private signing key that  
1737 is associated with an application-layer certificate to be stored into the secure vault using security  
1738 controls that are available on the MG24. This integration ensures that application-layer credentials can  
1739 be provisioned into the vault securely such that no key material is misused or exposed.

1740 Because the device is prepared for application-layer onboarding on behalf of a specific, pre-defined  
1741 customer in Build 4 and this ownership information is sealed into device firmware, the device is  
1742 permanently identified as being owned by that customer.

### 1743 6.4.2 Streamline Application-Layer Onboarding

1744 Support for streamlined application-layer onboarding does not necessarily present such a burden on the  
1745 device manufacturer to provision application-layer onboarding software and/or credentials to the device  
1746 at manufacturing time. If desired, the manufacturer could pre-install application-layer bootstrapping  
1747 information onto the device at manufacturing time, as must be done in the independent application-  
1748 layer onboarding case. Alternatively, the device manufacturer may simply ensure that the device has the  
1749 capability to generate one-time application-layer bootstrapping information at runtime and use the  
1750 secure exchanges inherent in trusted network-layer onboarding to support application-layer  
1751 onboarding.

## 1752 **7 Additional Build Considerations**

1753 The Trusted Internet of Things (IoT) Device Network-Layer Onboarding and Lifecycle Management  
1754 project is now complete, so no additions or changes to the existing builds are planned as part of this  
1755 project effort. As trusted network-layer onboarding is increasingly adopted, however, others may wish  
1756 to continue implementation efforts to develop new build capabilities or enhance existing ones, so it is  
1757 worth noting potential areas of further work. Various ways in which individual builds could be enhanced  
1758 are noted in the appendices that detail each build's technologies and architectures. For example, some  
1759 builds could be enhanced by the addition of architectural components that they have not yet  
1760 implemented, such as secure device storage; the use of an independent, third-party certificate signing  
1761 authority; support for network-layer onboarding using Thread MeshCoP; support for application-layer  
1762 onboarding; and support (or enhanced support) for ongoing device authorization. In addition to adding  
1763 components to support these capabilities, future work could potentially involve demonstration of  
1764 application-layer onboarding using the FIDO Alliance's FIDO Device Onboard (FDO) specification and/or  
1765 the Connectivity Standards Alliance (CSA) MATTER specification. Other future work could involve  
1766 integrating additional security mechanisms with network-layer onboarding, beginning at device boot-up  
1767 and extending through all phases of the device lifecycle, to further protect the device and, by extension,  
1768 the network. For example, future builds could include the capability to demonstrate the integration of  
1769 trusted network-layer onboarding with zero trust-inspired capabilities such as those described in the  
1770 following subsections. In addition, the scope of implementation efforts could potentially be expanded  
1771 beyond the current focus on IP-based networks. While this project's goal has been to tackle what is  
1772 currently implementable, the subsections that follow briefly discuss areas that could potentially be  
1773 addressed by others in the future.

### 1774 **7.1 Network Authentication**

1775 Future builds could be designed to demonstrate network authentication in addition to device  
1776 authentication as part of the network-layer onboarding process. Network authentication enables the  
1777 device to verify the identity of the network that will be taking control of it prior to permitting itself to be  
1778 onboarded.

### 1779 **7.2 Device Communications Intent**

1780 Future builds could be designed to demonstrate the use of network-layer onboarding protocols to  
1781 securely transmit device communications intent information from the device to the network (i.e., to  
1782 transmit this information in encrypted form with integrity protections). Secure conveyance of device  
1783 communications intent information, combined with enforcement of it, would enable the build to ensure  
1784 that IoT devices are constrained to sending and receiving only those communications that are explicitly  
1785 required for each device to fulfill its purpose. Build 5 currently enforces device communications intent as  
1786 part of its continuous assurance process. Build 5 determines device communications intent information  
1787 (e.g., the device's MUD file URL) based on device type rather than conveying this information from the  
1788 device to the network during onboarding.

### 1789 **7.3 Network Segmentation**

1790 Future builds could demonstrate the ability of the onboarding network to dynamically assign each new  
1791 device that is permitted to join the network to a specific subnetwork. The router may have multiple  
1792 network segments configured to which an onboarded device may be dynamically assigned. The decision  
1793 regarding which segment (subnetwork) to which to assign the device could potentially be based on the  
1794 device's DHCP fingerprint, other markers of the device's type, or some indication of the device's  
1795 trustworthiness, subject to organizational policy.

### 1796 **7.4 Integration with a Lifecycle Management Service**

1797 Future builds could demonstrate trusted network-layer onboarding of a device, followed by streamlined  
1798 trusted application-layer onboarding of that device to a lifecycle management application service. Such  
1799 a capability would ensure that, once connected to the local network, the IoT device would automatically  
1800 and securely establish an association with a trusted lifecycle management service that is designed to  
1801 keep the device updated and patched on an ongoing basis.

### 1802 **7.5 Network Credential Renewal**

1803 Some devices may be provisioned with network credentials that are X.509 certificates and that will,  
1804 therefore, eventually expire. Future build efforts could explore and demonstrate potential ways of  
1805 renewing such credentials without having to reprovision the credentials to the devices.

### 1806 **7.6 Integration with Supply Chain Management Tools**

1807 Future work could include definition of an open, scalable supply chain integration service that can  
1808 provide additional assurance of device provenance and trustworthiness automatically as part of the  
1809 onboarding process. The supply chain integration service could be integrated with the authorization  
1810 service to ensure that only devices whose provenance meets specific criteria and that reach a threshold  
1811 level of trustworthiness will be onboarded or authorized.

### 1812 **7.7 Attestation**

1813 Future builds could integrate device attestation capabilities with network-layer onboarding to ensure  
1814 that only IoT devices that meet specific attestation criteria are permitted to be onboarded. In addition  
1815 to considering the attestation of each device as a whole, future attestation work could also focus on  
1816 attestation of individual device components, so that detailed attestation could be performed for each  
1817 board, integrated circuit, and software program that comprises a device.

### 1818 **7.8 Mutual Attestation**

1819 Future builds could implement mutual attestation of the device and its application services. In one  
1820 direction, device attestation could be used to enable a high-value application service to determine  
1821 whether a device should be given permission to access it. In the other direction, attestation of the  
1822 application service could be used to enable the device to determine whether it should give the  
1823 application service permission to access and update the device.

## 1824 **7.9 Behavioral Analysis**

1825 Future builds could integrate artificial intelligence (AI) and machine learning (ML)-based tools that are  
1826 designed to analyze device behavior to spot anomalies or other potential signs of compromise. Any  
1827 device that is flagged as a potential threat by these tools could have its network credentials invalidated  
1828 to effectively evict it from the network, be quarantined, or have its interaction with other devices  
1829 restricted in some way.

## 1830 **7.10 Device Trustworthiness Scale**

1831 Future efforts could incorporate the concept of a device trustworthiness scale in which information  
1832 regarding device capabilities, secure firmware updates, the existence (or not) of a secure element for  
1833 private key protection, type and version of each of the software components that comprise the device,  
1834 etc., would be used as input parameters to calculate each device's trustworthiness value. Calculating  
1835 such a value would essentially provide the equivalent of a background check. A history for the device  
1836 could be maintained, including information about whether it has ever been compromised, if it has a  
1837 known vulnerability, etc. Such a trustworthiness value could be provided as an onboarding token or  
1838 integrated into the authorization service so permission to onboard to the network, or to access certain  
1839 resources once joined, could be granted or denied based on historical data and trustworthiness  
1840 measures.

## 1841 **7.11 Resource Constrained Systems**

1842 At present, onboarding solutions for technologies such as Zigbee, Z-Wave, and BLE use their own  
1843 proprietary mechanisms or depend on gateways. In the future, efforts could be expanded to include  
1844 onboarding in highly resource-constrained systems and non-IP systems without using gateways. Future  
1845 work could include trying to perform trusted onboarding in these smaller microcontroller-constrained  
1846 spaces in a standardized way with the goal of bringing more commonality across various solutions  
1847 without having to rely on IP gateways.

1849 **Appendix B Glossary**

<b>Application-Layer Bootstrapping Information</b>	Information that the device and an application-layer service must have in order for them to mutually authenticate and use a trusted application-layer onboarding protocol to onboard a device at the application layer. There is application-layer bootstrapping information about the device that the network must be in possession of, and application-layer bootstrapping information about the application service that the device must be in possession of. A typical example of application-layer bootstrapping information that the device must have is the public key that corresponds to the trusted application service's private key.
<b>Application-Layer Onboarding</b>	The process of providing IoT devices with the application-layer credentials they need to establish a secure (i.e., encrypted) association with a trusted application service. This document defines two types of application-layer onboarding: independent and streamlined.
<b>Independent Application-Layer Onboarding</b>	An application-layer onboarding process that does not rely on use of the network-layer onboarding process to transfer application-layer bootstrapping information between the device and the application service.
<b>Network-Layer Bootstrapping Information</b>	Information that the device and the network must have in order for them to use a trusted network-layer onboarding protocol to onboard a device. There is network-layer bootstrapping information about the device that the network must be in possession of, and network-layer bootstrapping information about the network that the device must be in possession of. A typical example of device bootstrapping information that the network must have is the public key that corresponds with the device's private key.
<b>Network-Layer Onboarding</b>	The process of providing IoT devices with the network-layer credentials and policy they need to join a network upon deployment.
<b>Streamlined Application-Layer Onboarding</b>	An application-layer onboarding process that uses the network-layer onboarding protocol to securely transfer application-layer bootstrapping information between the device and the application service.
<b>Trusted Network-Layer Onboarding</b>	A network-layer onboarding process that meets the following criteria: <ul style="list-style-type: none"> <li>• provides each device with unique network credentials,</li> <li>• enables the device and the network to mutually authenticate,</li> <li>• sends devices their network credentials over an encrypted channel,</li> <li>• does not provide any person with access to the network credentials, and</li> <li>• can be performed repeatedly throughout the device lifecycle to enable: <ul style="list-style-type: none"> <li>• the device's network credentials to be securely managed and replaced as needed, and</li> <li>• the device to be securely onboarded to other networks after being repurposed or resold.</li> </ul> </li> </ul>

## 1850 Appendix C Build 1 (Wi-Fi Easy Connect, Aruba/HPE)

### 1851 C.1 Technologies

1852 Build 1 is an implementation of network-layer onboarding that uses the Wi-Fi Easy Connect protocol.  
 1853 The onboarding infrastructure and related technology components for Build 1 have been provided by  
 1854 Aruba/HPE. IoT devices that were onboarded using Build 1 were provided by Aruba/HPE and CableLabs.  
 1855 The CA used for signing credentials issued to IoT devices was provided by SEALSQ, a subsidiary of  
 1856 WISeKey. For more information on these collaborators and the products and technologies that they  
 1857 contributed to this project overall, see [Section 3.4](#).

1858 Build 1 network onboarding infrastructure components within the NCCoE lab consist of the Aruba  
 1859 Access Point. Build 1 also requires support from Aruba Central and the UXI Cloud, which are accessed via  
 1860 the internet. IoT devices that can be network-layer onboarded using Build 1 include the Aruba/HPE UXI  
 1861 sensor and CableLabs Raspberry Pi. The UXI sensor also includes the Aruba UXI Application, which  
 1862 enables it to use independent (see [Section 3.3.2](#)) application-layer onboarding to be onboarded at the  
 1863 application layer as well, providing that the network to which the UXI sensor is onboarded has  
 1864 connectivity to the UXI Cloud via the internet. The Build 1 implementation supports the provisioning of  
 1865 all three types of network credentials defined in DPP:

- 1866     ▪ Connector for DPP-based network access
- 1867     ▪ Password/passphrase/PSK for WPA3/WPA2 network access
- 1868     ▪ X.509 certificates for 802.1X network access

1869 Build 1 has been integrated with the SEALSQ CA on SEALSQ INeS CMS to enable Build 1 to obtain signed  
 1870 certificates from this CA when Build 1 is onboarding devices and issuing credentials for 802.1X network  
 1871 access. When issuing credentials for DPP and WPA3/WPA2-based network access, the configurator does  
 1872 not need to use a CA.

1873 Table C-1 lists the technologies used in Build 1. It lists the products used to instantiate each component  
 1874 of the reference architecture and describes the security function that the component provides. The  
 1875 components listed are logical. They may be combined in physical form, e.g., a single piece of hardware  
 1876 may house a network onboarding component, a router, and a wireless access point.

1877 **Table C-1 Build 1 Products and Technologies**

Component	Product	Function
Network-Layer Onboarding Component (Wi-Fi Easy Connect Configurator)	Aruba Access Point with support from Aruba Central	Runs the Wi-Fi Easy Connect network-layer onboarding protocol to interact with the IoT device to perform one-way or mutual authentication, establish a secure channel, and securely provide local network credentials to the device. If the network credential that is being provided to the device is a certificate, the onboarding component will interact with a certificate authority to sign the certificate. The configurator deployed in Build 1 supports DPP 2.0, but it is also backward compatible with DPP 1.0.

Component	Product	Function
Access Point, Router, or Switch	Aruba Access Point	Wireless access point that also serves as a router. It may get configured with per-device access control lists (ACLs) and policy when devices are onboarded.
Supply Chain Integration Service	Aruba Central	The device manufacturer provides device bootstrapping information to the HPE Cloud via the REST API that is documented in the DPP specification. Once the device is transferred to an owner, the HPE Cloud provides the device bootstrapping information (i.e., the device's DPP URI) to the device owner's private tenancy within the HPE Cloud.
Authorization Service	Cloud Auth (on Aruba Central)	The authorization service provides the configurator and router with the information needed to determine if the device is authorized to be onboarded to the network and, if so, whether it should be assigned any special roles or be subject to any specific access controls. It provides device authorization, role-based access control, and policy enforcement.
Build-Specific IoT Device	Aruba UXI Sensor	The IoT device that is used to demonstrate both trusted network-layer onboarding and trusted application-layer onboarding. It runs the Wi-Fi Easy Connect network-layer onboarding protocol supported by the build to securely receive its network credentials. It also has an application that enables it to perform independent (see <a href="#">Section 3.3.2</a> ) application-layer onboarding.
Generic IoT Device	Raspberry Pi	The IoT device that is used to demonstrate only trusted network-layer onboarding.
Secure Storage	Aruba UXI Sensor Trusted Platform Module (TPM)	Storage on the IoT device that is designed to be protected from unauthorized access and capable of detecting attempts to hack or modify its contents. Used to store and process private keys, credentials, and other information that must be kept confidential.
Certificate Authority (CA)	SEALSQ INeS CMS CA	Issues and signs certificates as needed. These certificates can be used by the device to connect to any 802.1a-based network.
Application-Layer Onboarding Service	UXI Application and UXI Cloud	After connecting to the network, the device downloads its application-layer credentials from the UXI cloud and uses them to authenticate to the UXI application, with which it interacts.

Component	Product	Function
Ongoing Device Authorization	N/A – Not intended for inclusion in this build	Performs activities designed to provide an ongoing assessment of the device’s trustworthiness and authorization to access network resources. For example, it may perform behavioral analysis or device attestation and use the results to determine whether the device should be granted access to certain high-value resources, assigned to a particular network segment, or other action taken.
Manufacturer Factory Provisioning Process	N/A (Not implemented at the time of publication)	Manufactures the IoT device. Creates, signs, and installs the device’s unique identity and other birth credentials into secure storage. Installs information the device requires for application-layer onboarding (if applicable). May populate a manufacturer database with information regarding devices that are created and, when the devices are sold, may record what entity owns them.

## 1878 C.2 Build 1 Architecture

### 1879 C.2.1 Build 1 Logical Architecture

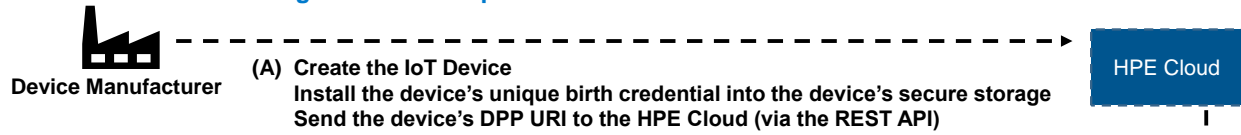

1880 The network-layer onboarding steps that are performed in Build 1 are depicted in [Figure C-1](#). These  
 1881 steps are broken into two main parts: those required to transfer device bootstrapping information from  
 1882 the device manufacturer to the device owner’s authorization service (labeled with letters) and those  
 1883 required to perform network-layer onboarding of the device (labeled with numbers).

1884 The device manufacturer:

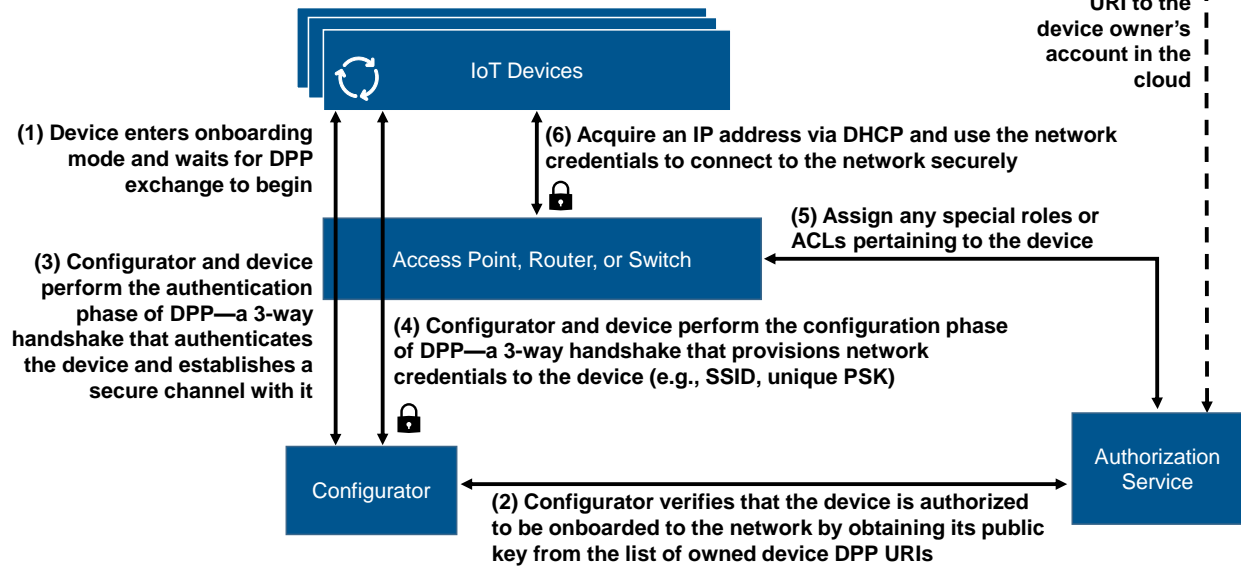

- 1885 1. Creates the device and installs a unique birth credential into secure storage on the device. Then  
 1886 the manufacturer sends the device’s bootstrapping information, which takes the form of a DPP  
 1887 URI, to Aruba Central in the HPE cloud. The device manufacturer interfaces with the HPE cloud  
 1888 via a REST API.
- 1889 2. When the device is purchased, the device’s DPP URI is sent to the HPE cloud account of the  
 1890 device’s owner. The device owner’s cloud account contains the DPP URIs for all devices that it  
 1891 owns.

1892 Figure C-1 Logical Architecture of Build 1

**IoT Device Manufacturing and Ownership Transfer Activities**

**Network-Layer Onboarding Steps**

1893 After obtaining the device, the device owner provisions the device with its network credentials by  
 1894 performing the following network-layer onboarding steps:

- 1895 1. The owner puts the device into onboarding mode. The device waits for the DPP exchange to  
 1896 begin. This exchange includes the device issuing a discovery message, which the owner's  
 1897 configurator hears. The discovery message is secured such that it can only be decoded by an  
 1898 entity that possesses the device's DPP URI.
- 1899 2. The configurator consults the list of DPP URIs of all owned devices to decode the discovery  
 1900 message and verify that the device is owned by the network owner and is therefore assumed to  
 1901 be authorized to be onboarded to the network.
- 1902 3. Assuming the configurator finds the device's DPP URI, the configurator and the device perform  
 1903 the authentication phase of DPP, which is a three-way handshake that authenticates the device  
 1904 and establishes a secure (encrypted) channel with it.
- 1905 4. The configurator and the device use this secure channel to perform the configuration phase of  
 1906 DPP, which is a three-way handshake that provisions network credentials to the device, along  
 1907 with any other information that may be needed, such as the network SSID.
- 1908 5. The router or switch consults the owner's authentication, authorization, and accounting (AAA)  
 1909 service to determine if the device should be assigned any special roles or if any special ACL  
 1910 entries should be made for the device. If so, these are configured on the router or switch.

1911 6. The device uses Dynamic Host Configuration Protocol (DHCP) to acquire an IP address and then  
1912 uses its newly provisioned network credentials to connect to the network securely.

1913 This completes the network-layer onboarding process.

1914 After the device is network-layer onboarded and connects to the network, it automatically performs  
1915 independent (see [Section 3.3.2](#)) application-layer onboarding. The application-layer onboarding steps  
1916 are not depicted in [Figure C-1](#). During the application-layer onboarding process, the IoT device, which is  
1917 a UXI sensor, authenticates itself to the UXI cloud using its manufacturing certificate and pulls its  
1918 application-layer credentials from the UXI cloud. In addition, if a firmware update is relevant, this also  
1919 happens. The UXI sensor contacts the UXI cloud service to download a customer-specific configuration  
1920 that tells it what to monitor on the customer's network. The UXI sensor then conducts the network  
1921 performance monitoring functions it is designed to perform and uploads the data it collects to the UXI  
1922 application dashboard.

## 1923 [C.2.2 Build 1 Physical Architecture](#)

1924 [Section 5.2](#) describes the physical architecture of Build 1.

## 1925 **Appendix D Build 2 (Wi-Fi Easy Connect, CableLabs, OCF)**

### 1926 **D.1 Technologies**

1927 Build 2 is an implementation of network-layer onboarding that uses the Wi-Fi Easy Connect protocol.  
 1928 Build 2 also supports streamlined (see [Section 3.3.2](#)) application-layer onboarding to the OCF security  
 1929 domain. The network-layer onboarding infrastructure for Build 2 is provided by CableLabs and the  
 1930 application-layer onboarding infrastructure is provided by OCF. IoT devices that were network-layer  
 1931 onboarded using Build 2 were provided by Aruba/HPE and OCF. Only the IoT devices provided by OCF  
 1932 were capable of being both network-layer onboarded and streamlined application-layer onboarded. For  
 1933 more information on these collaborators and the products and technologies that they contributed to  
 1934 this project overall, see [Section 3.4](#).

1935 Build 2 onboarding infrastructure components consist of the CableLabs Custom Connectivity Gateway  
 1936 Agent, which runs on the Gateway Access Point, and the Platform Controller. IoT devices onboarded by  
 1937 Build 2 include the Aruba UXI Sensor and CableLabs Raspberry Pi.

1938 Table D-1 lists the technologies used in Build 2. It lists the products used to instantiate each logical build  
 1939 component and the security function that the component provides. The components listed are logical.  
 1940 They may be combined in physical form, e.g., a single piece of hardware may house a network  
 1941 onboarding component, a router, and a wireless access point.

1942 **Table D-1 Build 2 Products and Technologies**

Component	Product	Function
Network-Layer Onboarding Component (Configurator)	CableLabs Custom Connectivity Gateway Agent with support from CableLabs Platform Controller	Runs the Wi-Fi Easy Connect network-layer onboarding protocol to interact with the IoT device to perform one-way or mutual authentication, establish a secure channel, and securely provide local network credentials to the device. It also securely conveys application-layer bootstrapping information to the device as part of the Wi-Fi Easy Connect protocol to support application-layer onboarding. The network-layer onboarding component deployed in Build 2 supports DPP 2.0, but it is also backward compatible with DPP 1.0.
Access Point, Router, or Switch	Raspberry Pi (running Custom Connectivity Gateway Agent)	The access point includes a configurator that runs the Wi-Fi Easy Connect Protocol. It also serves as a router that: 1) routes all traffic exchanged between IoT devices and the rest of the network, and 2) assigns each IoT device to a local network segment appropriate to the device's trust level (optional).

Component	Product	Function
Supply Chain Integration Service	CableLabs Platform Controller/IoTivity Cloud Service	The device manufacturer provides device bootstrapping information (i.e., the DPP URI) to the CableLabs Web Server. There are several potential mechanisms for sending the DPP URI to the CableLabs Web Server. The manufacturer can send the device's DPP URI to the Web Server directly, via an API. The API used is not the REST API that is documented in the DPP specification. However, the API is published and was made available to manufacturers wanting to onboard their IoT devices using Build 2. Once the device is transferred to an owner, the CableLabs Web Server provides the device's DPP URI to the device owner's authorization service, which is part of the owner's configurator.
Authorization Service	CableLabs Platform Controller	The authorization service provides the configurator and router with the information needed to determine if the device is authorized to be onboarded to the network and, if so, whether it should be assigned any special roles, assigned to any specific network segments, or be subject to any specific access controls.
Build-Specific IoT Device	Raspberry Pi (Bulb) Raspberry Pi (switch)	The IoT devices that are used to demonstrate both trusted network-layer onboarding and trusted application-layer onboarding. They run the Wi-Fi Easy Connect network-layer onboarding protocol to securely receive their network credentials. They also support application-layer onboarding of the device to the OCF environment by conveying the device's application-layer bootstrapping information as part of the network-layer onboarding protocol.
Generic IoT Device	Aruba UXI Sensor	The IoT device that is used to demonstrate only trusted network-layer onboarding.
Secure Storage	N/A (IoT device is not equipped with secure storage)	Storage designed to be protected from unauthorized access and capable of detecting attempts to hack or modify its contents. Used to store and process private keys and other information that must be kept confidential.
Certificate Authority	N/A (Not implemented at the time of publication)	Issues and signs certificates as needed.
Application-Layer Onboarding Service	OCF Diplomat and OCF OBT within IoTivity	After connecting to the network, the OCF Diplomat authenticates the devices, establishes secure channels with them, and sends them access control lists that control which bulbs each switch is authorized to turn on and off.

Component	Product	Function
Ongoing Device Authorization	N/A – Not intended for inclusion in this build	Performs activities designed to provide ongoing assessment of the device’s trustworthiness and authorization to access network resources. For example, it may perform behavioral analysis or device attestation and use the results to determine whether the device should be granted access to certain high-value resources, assigned to a particular network segment, or other action taken.
Manufacturer Factory Provisioning Process	N/A (Not yet implemented)	Manufactures the IoT device. Creates, signs, and installs the device’s unique identity and other birth credentials into secure storage. Installs information the device requires for application-layer onboarding (if applicable). May populate a manufacturer database with information regarding devices that are created and, when the devices are sold, may record what entity owns them.

## 1943 D.2 Build 2 Architecture

### 1944 D.2.1 Build 2 Logical Architecture

1945 The network-layer onboarding steps that are performed in Build 2 are depicted in [Figure D-1](#). These  
 1946 steps are broken into two main parts: those required to transfer device bootstrapping information from  
 1947 the device manufacturer to the device owner’s authorization service (labeled with letters) and those  
 1948 required to perform network-layer onboarding of the device (labeled with numbers).

1949 The device manufacturer:

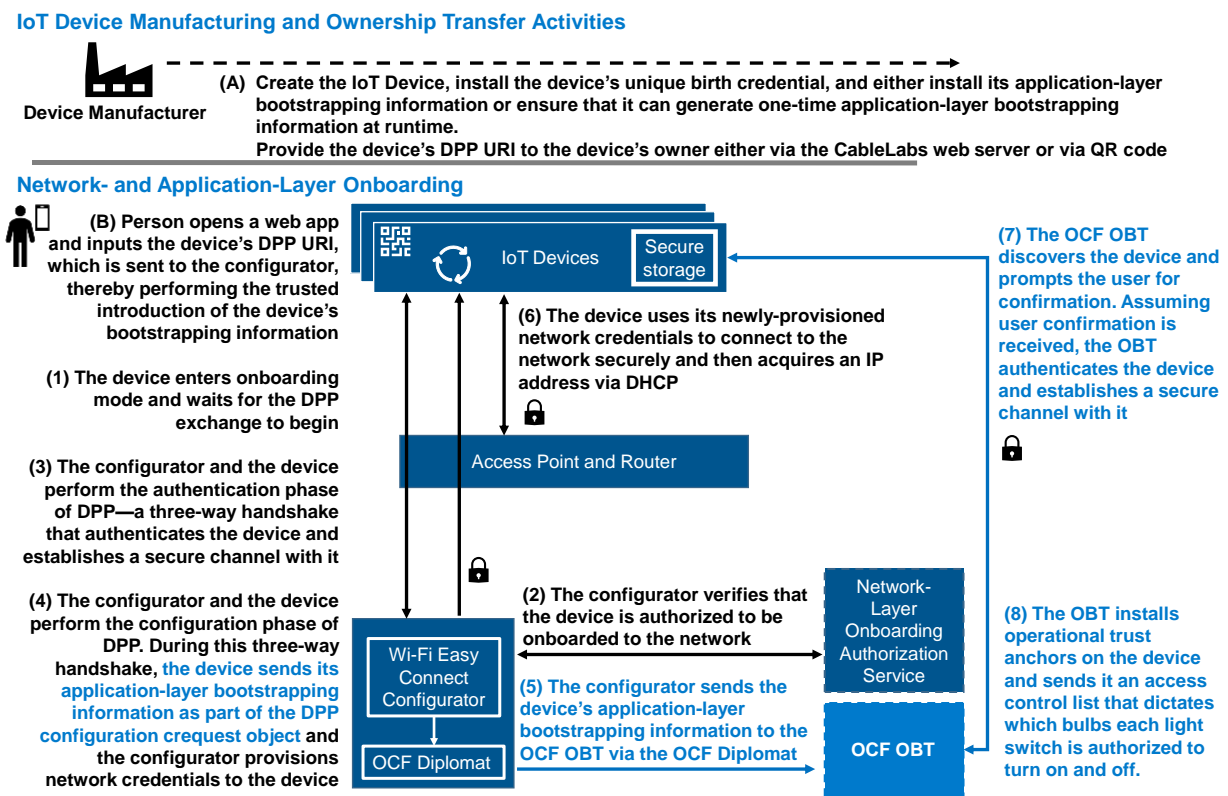

- 1950 1. Creates the device and installs a unique birth credential into secure storage on the device.  
 1951 Because the device created for use in Build 2 will also perform application-layer onboarding into  
 1952 the OCF security domain, as part of the manufacturing process the manufacturer also either  
 1953 installs application-layer bootstrapping information onto the device or ensures that the device  
 1954 has the capability to generate one-time application-layer bootstrapping information at runtime.  
 1955 Then the manufacturer makes the device’s network-layer bootstrapping information, which  
 1956 takes the form of a DPP URI, available to the device’s owner.

1957 Build 2 supports several mechanisms whereby the manufacturer can make the device’s  
 1958 network-layer bootstrapping information (i.e., its DPP URI) available to the device owner. The  
 1959 device’s DPP URI can be uploaded directly to a device owner’s cloud account or web server via  
 1960 API (as might come in handy when onboarding many enterprise devices at one time).  
 1961 Alternatively, the DPP URI can be manually entered into a local web portal that runs a  
 1962 configuration webpage that a device on the same Wi-Fi network can connect to for purposes of  
 1963 scanning a QR code or typing in the DPP URI. A DPP URI that is to be entered manually could, for  
 1964 example, be emailed to the owner or encoded into a QR code and printed on the device chassis,  
 1965 in device documentation, or on device packaging. Table D-1 depicts the case in which the  
 1966 manufacturer provides the device’s DPP URI to the owner for manual entry. When the owner  
 1967 receives the device’s DPP URI, the owner may optionally add the device’s DPP URI to a list of

1968 DPP URIs for devices that it owns that is maintained as part of the owner’s authorization service.  
 1969 Such a list would enable the owner’s network to determine if a device is authorized to be  
 1970 onboarded to it.

1971 2. The person onboarding the device opens a web application and enters the device’s DPP URI. The  
 1972 web application then sends the DPP URI to the Wi-Fi Easy Connect configurator, e.g., through a  
 1973 web request. (Note: Although the laboratory implementation of Build 2 requires the user to  
 1974 enter the DPP URI via a web page, an implementation designed for operational use would  
 1975 typically require the user to provide the DPP URI by scanning a QR code into a network  
 1976 operator-provided app that is logged into the user’s account.)

1977 **Figure D-1 Logical Architecture of Build 2**

1978 After ensuring that the device’s network-layer bootstrapping information (i.e., its DPP URI) has been  
 1979 uploaded to the configurator, the device owner performs both trusted network-layer onboarding and  
 1980 streamlined application-layer onboarding to the OCF security domain by performing the steps depicted  
 1981 in Figure D-1. In this diagram, the components that relate to network-layer onboarding are depicted in  
 1982 dark blue and their associated steps are written in black font. The components and steps that are  
 1983 related to application-layer onboarding are depicted in light blue. The steps are as follows:

1984 1. The owner puts the device into onboarding mode. The device waits for the DPP exchange to  
 1985 begin. This exchange includes the device issuing a discovery message, which the owner’s  
 1986 configurator hears. The discovery message is secured such that it can only be decoded by an  
 1987 entity that possesses the device’s DPP URI.

- 1988 2. Optionally, if such a list is being maintained, the configurator consults the list of DPP URIs of all  
 1989 owned devices to verify that the device is owned by the network owner and is, therefore,  
 1990 assumed to be authorized to be onboarded to the network. (If the device is being onboarded by  
 1991 an enterprise, the enterprise would likely maintain such a list; however, if the device is being  
 1992 onboarded to a home network, this step might be omitted.)
- 1993 3. Assuming the configurator finds the device's DPP URI, the configurator and the device perform  
 1994 the authentication phase of DPP, which is a three-way handshake that authenticates the device  
 1995 and establishes a secure (encrypted) channel with it.
- 1996 4. The configurator and the device use this secure channel to perform the configuration phase of  
 1997 DPP, which is a three-way handshake that provisions network credentials to the device, along  
 1998 with any other information that may be needed, such as the network SSID. In particular, as part  
 1999 of the three-way handshake in the Build 2 demonstration, the device sends its application-layer  
 2000 bootstrapping information to the configurator as part of the DPP configuration request object.
- 2001 5. The configurator receives the device's application-layer bootstrapping information and forwards  
 2002 it to the OCF Diplomat. The purpose of the OCF Diplomat is to provide a bridge between the  
 2003 network and application layers. It accomplishes this by parsing the org.openconnectivity fields of  
 2004 the DPP request object, which contains the UUID of the device and the application-layer  
 2005 bootstrapping credentials, and sending these to the OCF OBT as part of a notification that the  
 2006 OBT has a new device to onboard. The Diplomat and the OBT use a subscribe and notify  
 2007 mechanism to ensure that the OBT will receive the onboarding request even if the OBT is  
 2008 unreachable for a period of time (e.g., the OBT is out of the home).
- 2009 6. The device uses its newly provisioned network credentials to connect to the network securely  
 2010 and then uses DHCP to acquire an IP address. This completes the network-layer onboarding  
 2011 process.
- 2012 7. The OBT implements a filtered discovery mechanism using the UUID provided from the OCF  
 2013 Diplomat to discover the new device on the network. Once it discovers the device, before  
 2014 proceeding, the OBT may optionally prompt the user for confirmation that they want to perform  
 2015 application-layer onboarding to the OCF security domain. This prompting may be accomplished,  
 2016 for example, by sending a confirmation request to an OCF app on the user's mobile device.  
 2017 Assuming the user responds affirmatively, the OBT uses the application-layer bootstrapping  
 2018 information to authenticate the device and take ownership of it by setting up a Datagram  
 2019 Transport Layer Security (DTLS) connection with the device.
- 2020 8. The OBT then installs operational trust anchors and access control lists onto the device. For  
 2021 example, in the access control list, each light bulb may have an access control entry dictating  
 2022 which light switches are authorized to turn it on and off. This completes the application-layer  
 2023 onboarding process.
- 2024 Note that, at this time, the application-layer bootstrapping information is provided unilaterally in the  
 2025 Build 2 application-layer onboarding demonstration. The application-layer bootstrapping information of  
 2026 the device is provided to the OCF Diplomat, enabling the OBT to authenticate the device. In a future  
 2027 version of this process, the application-layer bootstrapping information could be provided bi-

2028 directionally, meaning that the OCF Diplomat could also send the OCF operational root of trust to the  
2029 IoT device as part of the DPP configuration response frame. Exchanging application-layer bootstrapping  
2030 information bilaterally in this way would enable the secure channel set up as part of the network-layer  
2031 onboarding process to support establishment of a mutually authenticated session between the device  
2032 and the OBT.

2033 In the Build 2 demonstration, two IoT devices, a switch and a light bulb, are onboarded at both the  
2034 network and application layers. Each of these devices sends the OCF Diplomat its application-layer  
2035 bootstrapping information over the secure network-layer onboarding channel during the network-layer  
2036 onboarding process. Immediately after they complete the network-layer onboarding process and  
2037 connect to the network, the OCF Diplomat provides their application-layer bootstrapping information to  
2038 the OBT. The OBT then uses the provided application-layer bootstrapping information to discover,  
2039 authenticate, and onboard each device. Because the devices have no way to authenticate the identity of  
2040 the OBT in the current implementation, the devices are configured to trust the OBT upon first use.

2041 After the OBT authenticates the devices, it establishes secure channels with them and provisions them  
2042 access control lists that control which bulbs each switch is authorized to turn on and off. To demonstrate  
2043 that the application onboarding was successful, Build 2 demonstrates that the switch is able to control  
2044 only those bulbs that the OCF OBT has authorized it to.

## 2045 [D.2.2 Build 2 Physical Architecture](#)

2046 [Section 5.3](#) describes the physical architecture of Build 2.

## 2047 **Appendix E Build 3 (BRSKI, Sandelman Software Works)**

### 2048 **E.1 Technologies**

2049 Build 3 is an implementation of network-layer onboarding that uses the BRSKI protocol. Build 3 does not  
 2050 support application-layer onboarding. The network-layer onboarding infrastructure and related  
 2051 technology components for Build 3 were provided by Sandelman Software Works. The Raspberry Pi,  
 2052 ESP32, and Nordic NRF IoT devices that will be onboarded in a future implementation of Build 3 were  
 2053 also provided by Sandelman Software Works, as was the Sandelman Software Works Reach Pledge  
 2054 Simulator, which is the device that is onboarded in the current build. The IoT devices do not have secure  
 2055 storage, but future plans are to integrate them with secure storage elements. Build 3 issues private PKI  
 2056 certificates as network credentials at this time, but future plans are to integrate Build 3 with a third-  
 2057 party private CA from which it can obtain signed certificates. For more information on Sandelman  
 2058 Software Works and the products and technologies that it contributed to this project overall, see [Section](#)  
 2059 [3.4.](#)

2060 Onboarding Build 3 infrastructure components consist of Raspberry Pi, Nordic NRF, ESP32, Sandelman  
 2061 Software Works Minerva Fountain Join Registrar/Coordinator, Sandelman Software Works Minerva.  
 2062 Highway, Sandelman Software Works Reach Pledge Simulator, and a Minerva Fountain internal CA.

2063 Table E-1 lists the technologies used in Build 3. It lists the products used to instantiate each logical build  
 2064 component and the security function that the component provides. The components are logical. They  
 2065 may be combined in physical form, e.g., a single piece of hardware may house both a network  
 2066 onboarding component and a router and/or wireless access point.

2067 **Table E-1 Build 3 Products and Technologies**

Component	Product	Function
Network-Layer Onboarding Component (BRSKI Domain Registrar)	Sandelman Software Works Minerva Fountain Registrar	Runs the BRSKI protocol. It authenticates the IoT device, receives a voucher-request from the IoT device, and passes the request to the MASA. It also receives a voucher from the MASA, verifies it, and passes it to the IoT device. Assuming the IoT device finds the voucher to be valid and determines that the network is authorized to onboard it, the Domain Registrar provisions network credentials to the IoT device using EST.
Access Point, Router, or Switch	Turris MOX router running OpenWRT	The Onboarding Router segments the onboarding device from the rest of the network until the BRSKI onboarding is complete

Component	Product	Function
Supply Chain Integration Service (Manufacturer Authorized Signing Authority—MASA)	Minerva Highway, which is a MASA provided by Sandelman Software Works	The device manufacturer provides device bootstrapping information (e.g., the device's X.509 certificate) and device ownership information to the MASA. The MASA creates and signs a voucher saying who the owner of the device is and provides this voucher to the IoT device via the Domain Registrar so that the device can verify that the network that is trying to onboard it is authorized to do so.
Authorization Service	Minerva Highway, which is a MASA provided by Sandelman Software Works	As described in the previous row.
IoT Device (Pledge)	Sandelman Software Works Reach Pledge Simulator	The device that is used to demonstrate trusted network-layer onboarding by joining the network.
Secure Storage	N/A (The IoT devices and the Sandelman Software Works Reach Pledge Simulator do not include secure storage)	Storage on the IoT device that is designed to be protected from unauthorized access and capable of detecting attempts to hack or modify its contents. Used to store and process private keys, credentials, and other information that must be kept confidential.
Certificate Authority	N/A (self-signed certificates were used)	Issues and signs certificates as needed.
Application-Layer Onboarding Service	None. Not supported in this build.	After connecting to the network, the device mutually authenticates with a trusted application service and interacts with it at the application layer.
Ongoing Device Authorization	N/A – Not intended for inclusion in this build	Performs activities designed to provide an ongoing assessment of the device's trustworthiness and authorization to access network resources. For example, it may perform behavioral analysis or device attestation and use the results to determine whether the device should be granted access to certain high-value resources, assigned to a particular network segment, or other action taken.
Manufacturer Factory Provisioning Process	N/A (Not implemented at the time of publication)	Manufactures the IoT device. Creates, signs, and installs the device's unique identity and other birth credentials into secure storage. Installs information the device requires for application-layer onboarding (if applicable). May populate a manufacturer database with information regarding devices that are created and, when the devices are sold, may record what entity owns them.

2068 **E.2 Build 3 Architecture**

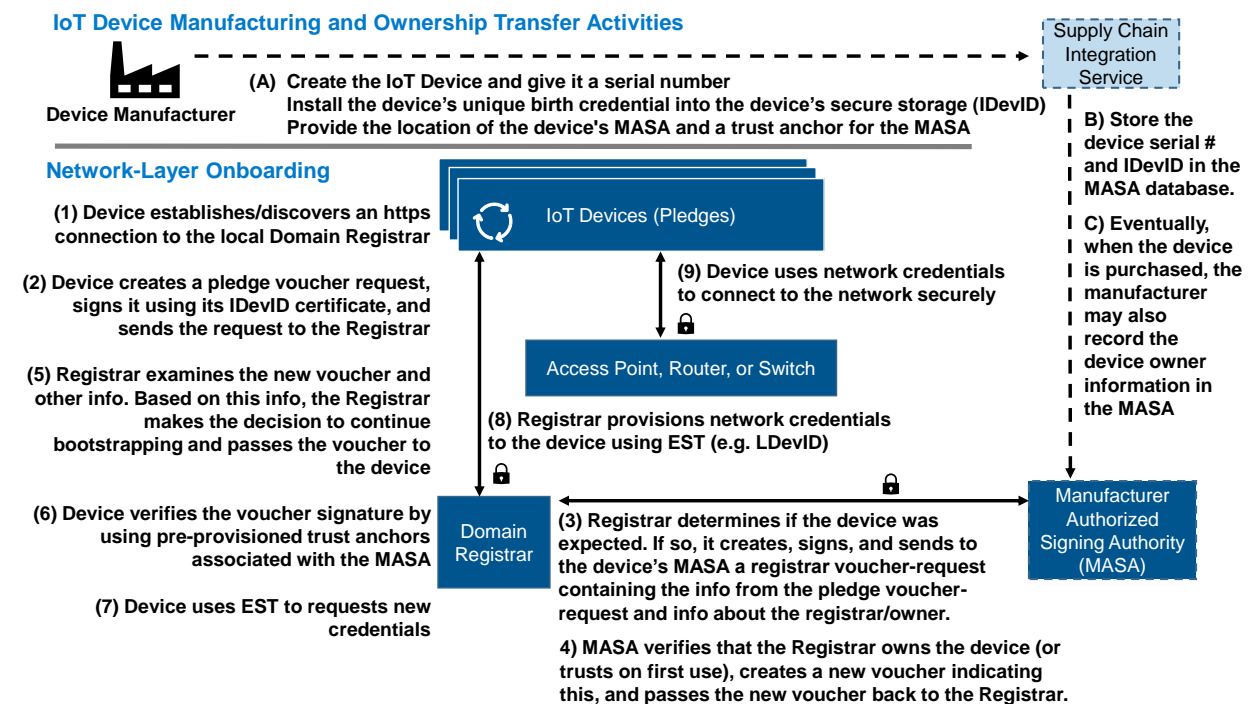

2069 **E.2.1 Build 3 Logical Architecture**

2070 The network-layer onboarding steps that are performed in Build 3 are depicted in Figure E-1. These  
 2071 steps are broken into two main parts: those required to transfer device bootstrapping information from  
 2072 the device manufacturer to the device owner’s authorization service (labeled with letters) and those  
 2073 required to perform network-layer onboarding of the device (labeled with numbers). These steps are  
 2074 described in greater detail in IETF RFC 8995.

2075 The device manufacturer:

- 2076 1. Creates the device and installs a unique serial number and birth credential into secure storage  
 2077 on the device. This unique birth credential takes the form of a private key and its associated  
 2078 802.1AR certificate, e.g., the device’s IDevID. As part of this factory-installed certificate process,  
 2079 the location of the device’s MASA is provided in an extension to the IDevID. The device is also  
 2080 provided with trust anchors for the MASA entity that will sign the returned vouchers.
- 2081 2. Stores information about the device, such as its serial number and its IDevID, in the MASA’s  
 2082 database.
- 2083 3. Eventually, when the device is sold, the MASA may also record the device ownership  
 2084 information in its database.

2085 **Figure E-1 Logical Architecture of Build 3**

2086 After obtaining the device, the device owner provisions the device with its network credentials by  
2087 performing the following network-layer onboarding steps:

- 2088 1. The owner puts the device into onboarding mode. The device establishes an https connection to  
2089 the local Domain Registrar. Trust in the Domain Registrar is provisional. (In a standard  
2090 implementation, the device would use link-local network connectivity to locate a join proxy, and  
2091 the join proxy would provide the device with https connectivity to the local Domain Registrar.  
2092 The Build 3 implementation, however, does not support discovery at this time. To overcome this  
2093 code limitation, the IoT device has been pre-provided with the address of the local Domain  
2094 Registrar, to which it connects directly.)
- 2095 2. The device creates a pledge voucher-request that includes the device serial number, signs this  
2096 request with its IDevID certificate (i.e., its birth credential), and sends this signed request to the  
2097 Registrar.
- 2098 3. The Registrar receives the pledge voucher-request and considers whether the manufacturer is  
2099 known to it and whether devices of that type are welcome. If so, the Registrar forms a registrar  
2100 voucher-request that includes all the information from the pledge voucher-request along with  
2101 information about the registrar/owner. The Registrar signs this registrar voucher-request. It  
2102 locates the MASA that the IoT device is known to trust (e.g., the MASA that is identified in the  
2103 device's IDevID extension) and sends the registrar voucher-request to the MASA.
- 2104 4. The MASA consults the information that it has stored and applies policy to determine whether  
2105 or not to approve the Registrar's claim that it owns and/or is authorized to onboard the device.  
2106 (For example, the MASA may consult sales records for the device to verify device ownership, or  
2107 it may be configured to trust that the first registrar that contacts it on behalf of a given device is  
2108 in fact the device owner.) Assuming the MASA decides to approve the Registrar's claim to own  
2109 and/or be authorized to onboard the device, the MASA creates a voucher that directs the device  
2110 to accept its new owner/authorized network, signs this voucher, and sends it back to the  
2111 Registrar.
- 2112 5. The Registrar receives this voucher, examines it along with other related information (such as  
2113 security posture, remote attestation results, and/or expected device serial numbers), and  
2114 determines whether it trusts the voucher. Assuming it trusts the voucher, the Registrar passes  
2115 the voucher to the device.
- 2116 6. The device uses its factory-provisioned MASA trust anchors to verify the voucher signature,  
2117 thereby ensuring that the voucher can be trusted. The voucher also validates the Registrar and  
2118 represents the intended owner, ending the provisional aspect of the EST connection.
- 2119 7. The device uses Enrollment over Secure Transport (EST) to request new credentials.
- 2120 8. The Registrar provisions network credentials to the device using EST. These network credentials  
2121 get stored into secure storage on the device, e.g., as an LDevID.
- 2122 9. The device uses its newly provisioned network credentials to connect to the network securely.

2123 This completes the trusted network-layer onboarding process for Build 3.

DRAFT

2124 [E.2.2 Build 3 Physical Architecture](#)

2125 [Section 5.4](#) describes the physical architecture of Build 3.

## 2126 **Appendix F Build 4 (Thread, Silicon Labs-Thread, Kudelski** 2127 **KeySTREAM)**

### 2128 **F.1 Technologies**

2129 Build 4 is an implementation of network-layer connection to an OpenThread network, followed by use  
2130 of the Kudelski IoT keySTREAM Service to perform independent (see [Section 3.3.2](#)) application-layer  
2131 onboarding of the device to a particular customer’s tenancy in the AWS IoT Core. To join the network,  
2132 the joining device generates and displays a pre-shared key that the owner enters on the commissioner,  
2133 through a web interface, for authentication. The network-layer infrastructure for Build 4 was provided  
2134 by Silicon Labs. The application-layer onboarding infrastructure for Build 4 was provided by Kudelski IoT.  
2135 IoT devices that were onboarded using Build 4 were provided by Silicon Labs. For more information on  
2136 these collaborators and the products and technologies that they contributed to this project overall, see  
2137 [Section 3.4](#).

2138 Build 4 network infrastructure components within the NCCoE lab consist of a Thread border router  
2139 (which is implemented using a Raspberry Pi) and a Silicon Labs Gecko Wireless Starter Kit. Build 4 also  
2140 requires support from the Kudelski IoT keySTREAM service to perform application-layer onboarding. The  
2141 keySTREAM service comes as a SaaS platform that is running in the cloud (accessible via the internet),  
2142 and a software library (KTA – Kudelski Trusted Agent) that is integrated in the IoT device software stack.  
2143 The KTA integrates with the Silicon Labs’ Hardware Root of Trust (Secure Vault). The IoT device that is  
2144 connected to the network and application-layer onboarded using Build 4 is the Silicon Labs  
2145 Thunderboard (BRD2601A) with EFR32MG24x with Secure Vault(TM) High which is security certified to  
2146 PSA/SESIP Level 3.

2147 Table F-1 lists the technologies used in Build 4. It lists the products used to instantiate each logical build  
2148 component and the security function that the component provides. The components are logical. They  
2149 may be combined in physical form, e.g., a single piece of hardware may house a network onboarding  
2150 component, a router, and a wireless access point.

2151 **Table F-1 Build 4 Products and Technologies**

Component	Product	Function
Network-Layer Onboarding Component (Thread Protocol Component)	SLWSTK6023A Thread Radio Transceiver (Wireless starter kit);	The SLWSTK6023A acts as a Thread radio transceiver or radio coprocessor (RCP), allowing the open thread boarder router host platform to form and communicate with a Thread network. If the Thread MeshCoP were running on this device, it would provision the IoT device with credentials for the Thread network.
Access Point, Router, or Switch	OpenThread Border Router (OTBR) hosted on a Raspberry Pi	Router that has interfaces both on the Thread network and on the IP network to act as a bridge between the Thread network and the public internet. This allows the IoT device that communicates using the Thread wireless protocol to communicate with cloud services.

Component	Product	Function
Supply Chain Integration Service	Silicon Labs Custom Parts Manufacturer Service (CPMS)	To support network-layer onboarding, the device manufacturer provides device bootstrapping information to the to the device owner.
Authorization Service	Not implemented	Enables the network to verify that the device that is trying to onboard to it is authorized to do so.
IoT Device	Silicon Labs Thunderboard (BRD2601A)	The IoT device that is used to demonstrate trusted network- and application-layer onboarding.
Secure Storage	Secure Vault™ High on Silicon Labs IoT device	Storage designed to be protected from unauthorized access and capable of detecting attempts to hack or modify its contents. Used to store and process private keys and other information that must be kept confidential.
Certificate Authority	Each tenant in the Kudelski keySTREAM service cloud has its own certificate signing authority	Issues and signs certificates as needed. For application-layer onboarding, the device owner has its own certificate signing authority in its portion of the Kudelski keySTREAM service cloud.
Application-Layer Onboarding Service	Kudelski keySTREAM Service	After connecting to the Thread network, the device performs application-layer onboarding by accessing the Kudelski keySTREAM service. The device and the keySTREAM service mutually authenticate; the keySTREAM service verifies the device's owner, generates an application-layer credential (i.e., an AWS certificate that is based on the device's chipset identity and owner) for the device, and provisions the device with this X.509 credential that will enable the device to access the owner's tenancy in the AWS IoT Core cloud.
Ongoing Device Authorization	N/A – Not intended for inclusion in this build	Performs activities designed to provide an ongoing assessment of the device's trustworthiness and authorization to access network resources. For example, it may perform behavioral analysis or device attestation and use the results to determine whether the device should be granted access to certain high-value resources, assign the device to a particular network segment, or take other action.

Component	Product	Function
Manufacturer Factory Provisioning Process	Silicon Labs Custom Parts Manufacturing Service (CPMS)	<p>Manufactures the IoT device. Creates, signs, and installs the device's unique identity and other birth credentials into secure storage. Installs software and information the device requires for application-layer onboarding. The "A" or "B" version birth certificate can be modified via their Custom Part Manufacturing Service (CPMS) to be unique per end device manufacturer and signed into their Root CA if desired.</p>

## 2152 F.2 Build 4 Architecture

### 2153 F.2.1 Build 4 Logical Architecture

2154 Build 4 demonstrates a device connecting to an OpenThread network. IoT devices generate and use a  
 2155 pre-shared key to connect to the OpenThread network of Build 4 using the Thread MeshCoP service.  
 2156 Once a device is connected to the OpenThread network of Build 4, it gets access to an IP network via a  
 2157 border router, and then performs application-layer onboarding using the Kudelski keySTREAM Service.  
 2158 Kudelski keySTREAM is a device security management service that runs as a SaaS platform on the  
 2159 Amazon cloud. Build 4 relies on an integration that has been performed between Silicon Labs and  
 2160 Kudelski keySTREAM. KeySTREAM has integrated software libraries with the Silicon Lab EFR32MG24  
 2161 (MG24) IoT device's secure vault to enable the private signing key that is associated with an application-  
 2162 layer certificate to be stored into the secure vault using security controls that are available on the  
 2163 MG24. This integration ensures that application-layer credentials can be provisioned into the vault  
 2164 securely such that no key material is misused or exposed.

2165 At a high level, the steps required to enable demonstration of Build 4's network connection and  
 2166 application-layer onboarding capabilities can be broken into the following three main parts:

- 2167     ▪ Device Preparation: The IoT device is prepared for network connection and application-layer  
 2168     onboarding by the device manufacturer.
  - 2169         • The device comes from the manufacturer ready to be provisioned onto a Thread network.  
 2170         No additional preparation is required.
  - 2171         • The device is prepared for application-layer onboarding on behalf of a specific, pre-defined  
 2172         customer who will become its owner. The device is assigned ownership to this customer  
 2173         (e.g., customer A) and this ownership information is sealed into device firmware,  
 2174         permanently identifying the device as being owned by customer A. The device owner,  
 2175         customer A, has a tenancy on the Kudelski keySTREAM Service and is also an Amazon Web  
 2176         Services (AWS) customer. After the device has been prepared, the device is provided to its  
 2177         owner (customer A).

2178       ▪ Network Connection: Customer A connects the device to Customer A’s OpenThread network by  
2179       entering the pre-shared key displayed on the device’s serial terminal in the OpenThread Border  
2180       Router’s (OTBR) web interface. This allows the network’s radio channel, PAN ID, extended PAN  
2181       ID and network name to be discovered, avoiding the need to preconfigure any of these  
2182       parameters. Once on customer A’s OpenThread network, the device has access to the public IP  
2183       network via the border router.

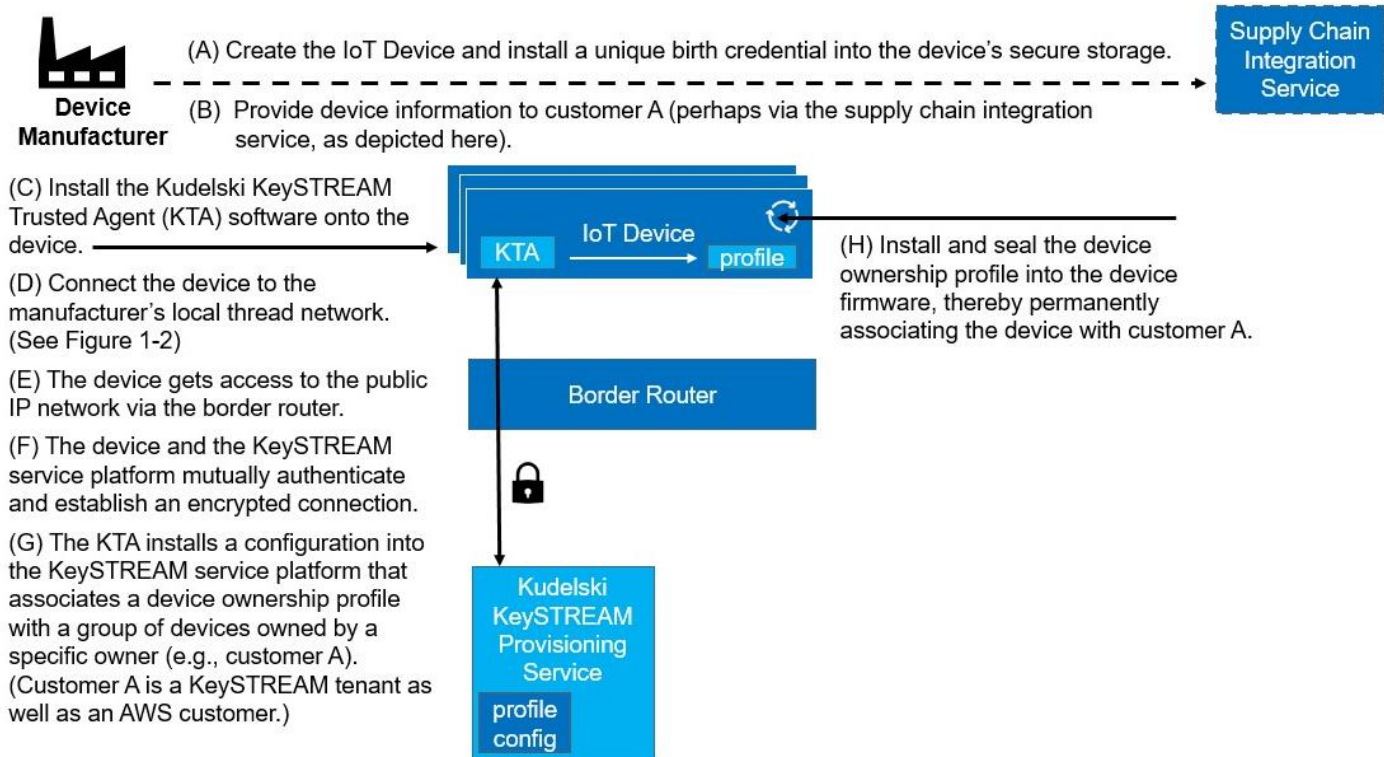

2184       ▪ Application-Layer Onboarding: The device and the keySTREAM service mutually authenticate,  
2185       keySTREAM confirms that customer A owns the device, and keySTREAM provisions the device  
2186       with an AWS certificate that is specific to the device and to customer A, enabling the device to  
2187       authenticate to customer A’s tenancy in the AWS IoT Core.

2188       Each of these three aspects of the demonstration are illustrated in its own figure and described in more  
2189       detail in the three subsections below.

### 2190       *F.2.1.1 Device Preparation*

2191       [Figure F-1](#) depicts the steps that are performed by the device manufacturer, which in this case is Silicon  
2192       Labs, to prepare the device for network- and application-layer onboarding by a particular customer,  
2193       Customer A. Each step is described in more detail below. Because these steps are performed to prepare  
2194       the device for onboarding rather than as part of onboarding itself, they are labeled with letters instead  
2195       of numbers in keeping with the conventions used in other build descriptions.

2196 Figure F-1 Logical Architecture of Build 4: Device Preparation

2197 The following steps are performed to prepare the device for network connection and application-layer  
 2198 onboarding:

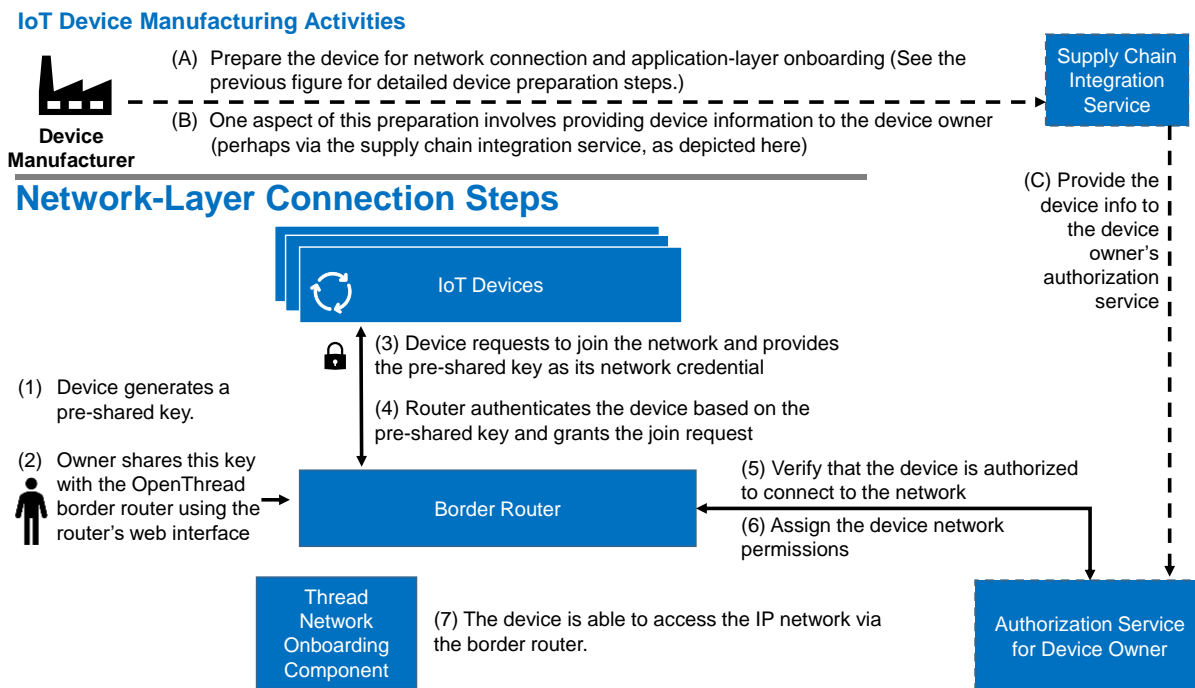

- 2199 1. The manufacturer creates the device, which in this case is a Silicon Labs MG24, and prepares it  
 2200 for network connection by installing the device's unique birth credential into the device's  
 2201 chipset. This chipset identity is a hardware root of trust. The MG24 "B" version comes pre-  
 2202 loaded with a Silicon Labs Birth certificate. The "A" or "B" version birth certificate can be  
 2203 modified via their Custom Part Manufacturing Service (CPMS) to be unique per end device  
 2204 manufacturer and signed into their Root CA if desired.
- 2205 2. The manufacturer provides information about the device to customer A (perhaps via the supply  
 2206 chain service, as depicted in Figure 1-1) so customer A can be aware that the device is expected  
 2207 on its network.
- 2208 3. The manufacturer prepares the device for application-layer onboarding by installing the Kudelski  
 2209 keySTREAM Trusted Agent (KTA) software onto the device.
- 2210 4. The manufacturer connects the device to the manufacturer's local OpenThread network. (See  
 2211 Figure 1-2 for details of the network connection steps.) Note that in this case, which is the first  
 2212 time that the device is being connected to a network, the device is being connected to the  
 2213 manufacturer's network rather than to the network of the device's eventual owner.
- 2214 5. After the device connects to the manufacturer's OpenThread network, the device has access to  
 2215 the public IP network via the border router.

- 2216 6. The device and the Kudelski keySTREAM service mutually authenticate and establish an  
2217 encrypted connection.
- 2218 7. The KTA installs a configuration into the keySTREAM service platform that builds up a group of  
2219 devices that belong to a certain end user and associates the group with a device ownership  
2220 profile. This device ownership profile is associated with a particular customer (e.g., customer A).  
2221 The same device profile is used by all devices in a group of devices that are owned by this  
2222 owner. The profile is not specific to individual devices. The owner of these devices (customer A)  
2223 has a keySTREAM tenancy, which includes a dedicated certificate signing CA. Customer A is also  
2224 an AWS customer.
- 2225 8. The device manufacturer installs and seals this device ownership profile into the device  
2226 firmware. This profile permanently identifies the device as being owned by customer A.

2227 **F.2.1.2 Network-Layer Connection**

2228 Figure F-2 depicts the steps of an IoT device connecting to that thread network using a pre-shared key  
2229 that the device generates and shares with the OpenThread border router. Each step is described in  
2230 more detail below.

2231 **Figure F-2 Logical Architecture of Build 4: Connection to the OpenThread Network**

- 2232 The device connects to the OpenThread network using the following steps:
- 2233 1. The device generates a pre-shared key.
  - 2234 2. The owner starts the commissioning process by entering this pre-shared key on the OpenThread  
2235 border router.

- 2236 3. The device requests to join the network and provides the pre-shared key as its network
- 2237 credential.
- 2238 4. The network authenticates the device based on the pre-shared key and grants the join request.
- 2239 5. The network verifies that the device is authorized to connect to the network.
- 2240 6. The network assigns the device network permissions and configures these as policies on the
- 2241 border router.
- 2242 7. The device is able to access the IP network (and the internet) via the border router.
- 2243 This completes the network-layer connection process.

### 2244 *F.2.1.3 Application-Layer Onboarding*

2245 Figure F-3 depicts the steps of the application-layer onboarding process using the Kudelski keySTREAM

2246 service. Each step is described in more detail below.

2247 **Figure F-3 Logical Architecture of Build 4: Application-Layer Onboarding using the Kudelski keySTREAM**

2248 **Service**

#### IoT Device Manufacturing Activities

Prepare the device for application-layer onboarding by sealing a device ownership profile that permanently associates the device with KeySTREAM customer A into the device's firmware. (See Figure 1-1 for the detailed device preparation steps.)

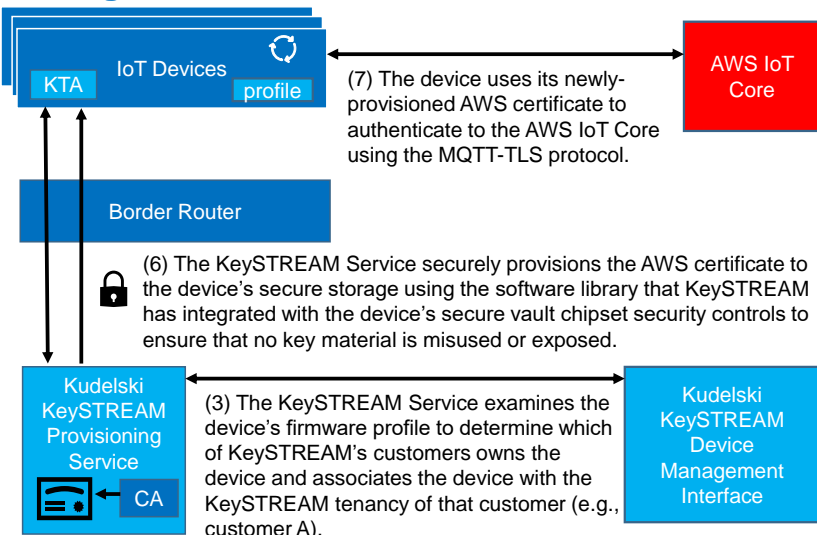

### Application-Layer Onboarding

(1) The device has already connected to the Thread network and now has access to the public (IP) network via the border router.

(2) The device and the KeySTREAM Service mutually authenticate.

(4) The KeySTREAM Service generates an AWS certificate for the device based on the device's chipset identity and owner.

(5) The KeySTREAM Service uses the dedicated CA that is running in customer A's KeySTREAM tenancy to sign the certificate.

2249 The application-layer onboarding steps performed to provision the device with its application-layer

2250 credentials (e.g., its AWS certificate) are as follows:

- 2251 1. The device, which is already connected to the OpenThread network, accesses the IP network via
- 2252 the border router.
- 2253 2. The device and the keySTREAM service mutually authenticate.

- 2254 3. The keySTREAM Service examines the device’s firmware profile to determine which of  
2255 keySTREAM’s customers owns the device. In this case, customer A is identified as the device  
2256 owner. The keySTREAM service associates the device with customer A’s keySTREAM tenancy.
- 2257 4. The keySTREAM Service generates an AWS IoT Core certificate for the device based on both the  
2258 device’s ownership information and the secure hardware root of trust that is in the device’s  
2259 chipset.
- 2260 5. The keySTREAM Service uses the dedicated CA that is running in customer A’s keySTREAM  
2261 tenancy to sign the AWS certificate.
- 2262 6. The keySTREAM Service securely provisions the AWS certificate to the device’s secure storage  
2263 using the software library that keySTREAM has integrated with the device’s secure vault chipset  
2264 security controls to ensure that no key material is misused or exposed.
- 2265 7. The device uses its newly provisioned application-layer credentials (i.e., the AWS certificate) to  
2266 authenticate to customer A’s tenancy in the AWS IoT Core using the MQTT-TLS protocol.

2267 **F.2.2 Build 4 Physical Architecture**

2268 [Section 5.5](#) describes the physical architecture of Build 4.

## 2269 Appendix G Build 5 (BRSKI over Wi-Fi, NquiringMinds)

### 2270 G.1 Technologies

2271 Build 5 is an implementation of network-layer onboarding that uses a version of the BRSKI Protocol that  
 2272 has been modified to work over Wi-Fi. After the IoT device has joined the network, Build 5 also  
 2273 demonstrates a number of mechanisms that are performed on an ongoing basis to provide continuous,  
 2274 policy-based authorization and assurance. Both the network-layer onboarding infrastructure and the  
 2275 continuous assurance service for Build 5 were provided by NquiringMinds. This entire build can be  
 2276 replicated using the open sourced [TrustNetZ code base](#).

2277 For more information on NquiringMinds and the products and technologies that they contributed to this  
 2278 project overall, see [Section 3.4](#).

2279 Build 5 network onboarding infrastructure components within the NCCoE lab consist of a Linux based  
 2280 Raspberry Pi 4B router (which also runs the registrar service and MASA service), and a USB hub. The  
 2281 Build 5 components used to support the continuous assurance service include TrustNetZ Authorization  
 2282 interfaces, TrustNetZ information provider, and TrustNetZ policy engine. The IoT devices that are  
 2283 onboarded using Build 5 are a Raspberry Pi device. These IoT devices do not have secure storage, but  
 2284 use the Infineon Optiga SLB 9670 TPM 2.0 as an external secure element. Build 5 depends on an IDevID  
 2285 (X.509 Certificate) having been provisioned to the secure element of the IoT device (pledge) prior to  
 2286 onboarding, as part of the factory provisioning process (see [Section H.1](#)). For Build 5, this factory  
 2287 provisioning process was accomplished by the BRSKI Factory Provisioning Build, which is described in  
 2288 [Appendix H.3](#).

2289 Table G-1 lists the technologies used in Build 5. It lists the products used to instantiate each logical build  
 2290 component and the security function that the component provides. The components are logical. They  
 2291 may be combined in physical form, e.g., a single piece of hardware may house a network onboarding  
 2292 component, a router, and a wireless access point.

2293 **Table G-1 Build 5 Products and Technologies**

Component	Product	Function
Network-Layer Onboarding Component (BRSKI Domain Registrar)	Stateful, non-persistent Linux app that has two functional interfaces for both BRSKI and for the Authentication Service. (TrustNetZ onboarding)	Runs the BRSKI protocol modified to work over Wi-Fi and acts as a BRSKI Domain Registrar. It authenticates the IoT device, receives a voucher request from the IoT device, and passes the request to the MASA. It also receives a voucher from the MASA, verifies it, and passes it to the IoT device. Assuming the IoT device finds the voucher to be valid and determines that the network is authorized to onboard it, the Domain Registrar provisions network credentials to the IoT device using EST.

Component	Product	Function
Access Point, Router, or Switch	Raspberry Pi 4B equipped with USB Wi-Fi dongle, running TrustNetZ AP code.	Router, providing an open Wi-Fi network and closed Wi-Fi network. Physical access control is mediated through the RADUIS interface (which is part of the TrustNetZ AP configuration) The AP also receives network commands from the continuous assurance service.
Supply Chain Integration Service (Manufacturer Authorized Signing Authority—MASA)	TrustNetZ MASA	The MASA creates and signs a voucher and provides this voucher to the IoT device via the Registrar so that the device can verify that the network that is trying to onboard it is authorized to do so.
Authorization Service	Linux application which contains an encapsulated policy engine (TrustNetZ policy engine)	Determines whether the device is authorized to be onboarded to the network. The application features a REST API which accepts verifiable credential claims to feed data on entities and their relationships into its SQL database. The policy engine itself is based on verifiable credentials presentation, (persisted to SQL database), making it easily configurable and extensible.
IoT Device	Raspberry Pi devices (running TrustNetZ pledge agent)	The IoT device that is used to demonstrate trusted network- and application-layer onboarding. Handles the client side BRSKI protocols, the integration with the secure storage, with factory provisioning and TLS connections.
Secure Storage	Infineon Optiga SLB 9670 TPM 2.0	Storage on the IoT device that is designed to be protected from unauthorized access and capable of detecting attempts to hack or modify its contents. Used to store and process private keys and other information that must be kept confidential.
Certificate Authority	TrustNetZ demo manufacturer CA (MPR – manufacture provisioning root) TrustNetZ Domain CA	Two CA are used in Build 5 Domain CA issues certificates and provides signing and attestation functions that model network owner relationships (e.g. sign the LDevID certificate) Manufacturer CA issues the IDevID certificates; proving the device has been created by the manufacturer.
Application-Layer Onboarding Service	TrustNetZ Demo application sever	After connecting to the network, the device mutually authenticates with a trusted application service and interacts with it at the application layer. The IDevID and TPM private key are used to establish a TLS session with the demonstration application server and send data to it from the device. This demonstrates the concept of secure connection to a third-party application server using the cryptographic artifacts from the onboarding process.

Component	Product	Function
Ongoing Device Authorization	Continuous Authorization Service, which calls into the in the TrustNetZ policy engine	<p>Designed to perform a set of ongoing, policy-based continuous assurance and authorization checks on the device after it has connected to the network. As of this publication, the following ongoing checks have been implemented:</p> <ul style="list-style-type: none"> <li>▪ The manufacturer of the device must be trusted by the network owner</li> <li>▪ The device must be trusted by a user with appropriate privileges</li> <li>▪ The device must have an associated device type</li> <li>▪ The vulnerability score of the software bill of materials (SBOM) for the device type must be lower than a set threshold</li> <li>▪ The device must not have contacted an IP address that is on a deny list</li> </ul> <p>If it fails any of these periodic checks, its voucher is revoked, which removes the device from the network.</p>
Manufacturer Factory Provisioning Process	BRSKI Factory Provisioning Process used to provision the Infineon TPM with its private key and IDevID (See <a href="#">Appendix H.3</a> )	Manufactures the IoT device. Creates, signs, and installs the device's unique identity (i.e., its IDevID, which is an X.509 certificate) into secure storage. Installs information the device requires for application-layer onboarding. Populates the MASA with information regarding devices that are created and, when the devices are sold, may record what entity owns them.

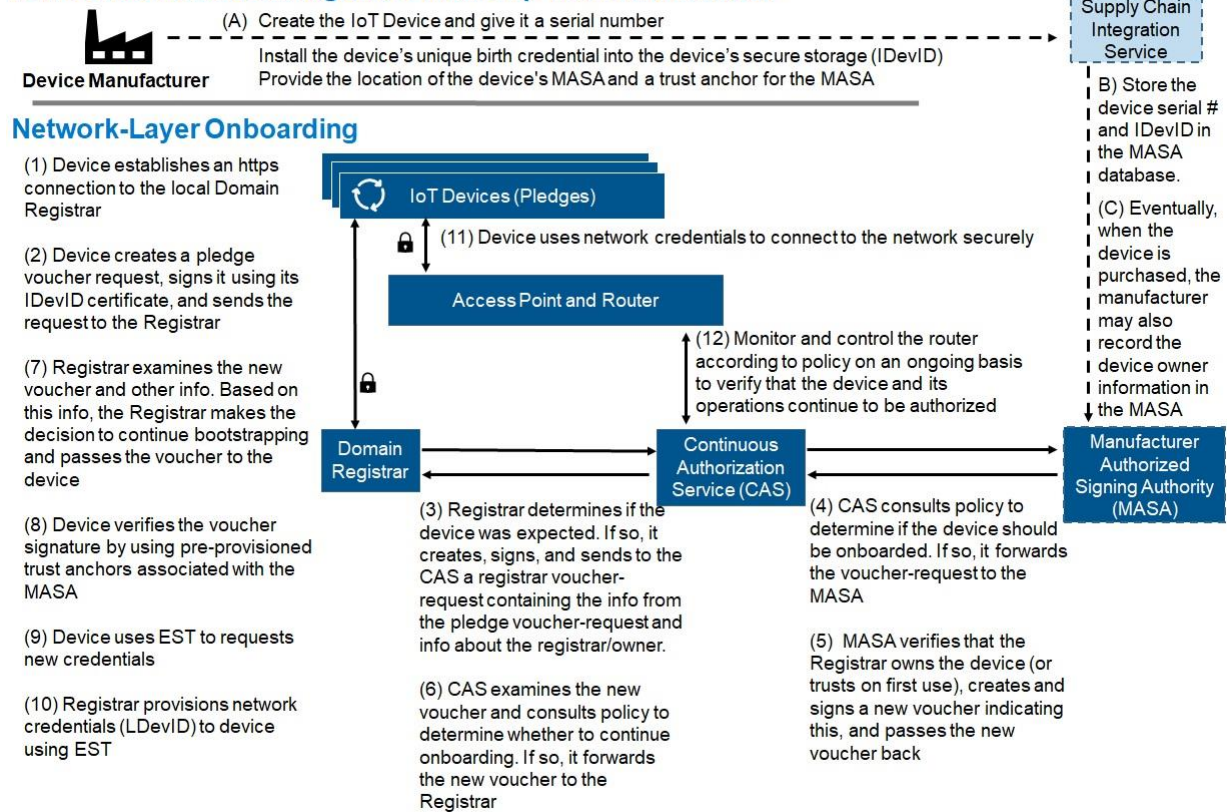

## 2294 G.2 Build 5 Architecture

### 2295 G.2.1 Build 5 Logical Architecture

2296 The network-layer onboarding steps that are performed in Build 5 are depicted in Figure G-1. These  
 2297 steps are broken into two main parts: those required to transfer device bootstrapping information from  
 2298 the device manufacturer to the MASA (labeled with letters) and those required to perform network-  
 2299 layer onboarding of the device and establish the operation of the continuous authorization service  
 2300 (labeled with numbers).

2301 Figure G-1 Logical Architecture of Build 5

### IoT Device Manufacturing and Ownership Transfer Activities

2302 The device manufacturer:

2303 1. Creates the device and installs a unique serial number and birth credential into secure storage  
 2304 on the device. This unique birth credential takes the form of a private key and its associated  
 2305 802.1AR certificate, e.g., the device's IDeVID. As part of this factory-installed certificate process,  
 2306 the location of the device's manufacturer authorized signing authority (MASA) is provided in an  
 2307 extension to the IDeVID. The device is also provided with trust anchors for the MASA entity that  
 2308 will sign the returned vouchers.

2309 2. Stores information about the device, such as its serial number and its IDeVID, in the MASA's  
 2310 database.

2311 3. Eventually, when the device is sold, the MASA may also record the device ownership  
 2312 information in its database.

2313 After obtaining the device, the device owner provisions the device with its network credentials by  
 2314 performing the following network-layer onboarding steps:

2315 1. The owner puts the device (i.e., the pledge) into onboarding mode. The device establishes an  
 2316 https connection to the local Domain Registrar. (In a standard BRSKI implementation, the device  
 2317 would have wired network connectivity. The device would use its link-local network connectivity  
 2318 to locate a join proxy, and the join proxy would provide the device with https connectivity to the

- 2319 local Domain Registrar.) The Build 5 implementation, however, relies on wireless connectivity  
2320 and initially uses the unauthenticated EAP-TLS protocol. The pledge discovers potential  
2321 onboarding networks by searching for public Wi-Fi networks that either match a particular SSID  
2322 wildcard name or that advertise a particular realm. When the device finds a potential  
2323 onboarding network, it connects to it and attempts to discover the registrar. The pledge will  
2324 connect to the open Wi-Fi network and will receive either an IPv4 or IPv6 address. Subsequently,  
2325 the pledge will listen to mDNS packets and will obtain the list of join proxies (IP addresses).  
2326 Finally, the pledge will subsequently connect to each join proxy using the BRSKI-EST protocol.
- 2327 2. The device creates a pledge voucher-request that includes the device serial number, signs this  
2328 request with its IDevID certificate (i.e., its birth credential), and sends this signed request to the  
2329 Registrar.
- 2330 3. The Registrar receives the pledge voucher-request and considers whether the manufacturer is  
2331 known to it and whether devices of that type are welcome. If so, the Registrar forms a registrar  
2332 voucher-request that includes all the information from the pledge voucher request along with  
2333 information about the registrar/owner. The Registrar sends this registrar voucher-request to the  
2334 Continuous Authorization Service.
- 2335 4. The Continuous Authorization Service consults policy to determine if this device should be  
2336 permitted to be onboarded and what other conditions should be enforced. An example of policy  
2337 that might be used is that the network owner wants to disable MASA validation. Assuming the  
2338 device is permitted to be onboarded, the Continuous Authorization Service locates the MASA  
2339 that the IoT device is known to trust (i.e., the MASA that is identified in the device's IDevID  
2340 extension) and sends the registrar voucher-request to the MASA.
- 2341 5. The MASA consults the information that it has stored and applies policy to determine whether  
2342 to approve the Registrar's claim that it owns the device. (For example, the MASA may consult  
2343 sales records for the device to verify device ownership, or it may be configured to trust that the  
2344 first registrar that contacts it on behalf of a given device is in fact the device owner). Assuming  
2345 the MASA decides to approve the Registrar's claim to own the device, the MASA creates a new  
2346 voucher that directs the device to accept its new owner, signs this voucher, and sends it back to  
2347 the Continuous Authorization Service.
- 2348 6. The Continuous Authorization Service receives this new voucher and examines it in consultation  
2349 with policy to determine whether to continue onboarding. Some examples of policies that might  
2350 be used include: permit onboarding only if no current critical vulnerabilities have been disclosed  
2351 against the declared device type, the device instance has successfully passed a site-specific test  
2352 process, or a test compliance certificate has been found for the declared device type. Assuming  
2353 the device is permitted to be onboarded, the Continuous Authorization Service sends the new  
2354 voucher to the Domain Registrar.
- 2355 7. The Domain Registrar receives and examines the new voucher along with other related  
2356 information and determines whether it trusts the voucher. Assuming it trusts the voucher, the  
2357 Registrar passes the voucher to the device.

- 2358 8. The device uses its factory-provisioned MASA trust anchors to verify the voucher signature,  
2359 thereby ensuring that the voucher can be trusted.
- 2360 9. The device uses Enrollment over Secure Transport (EST) to request new credentials.
- 2361 10. The Registrar provisions network credentials to the device using EST. These network credentials  
2362 get stored into secure storage on the device, e.g., as an LDevID.
- 2363 11. The device uses its newly provisioned network credentials to connect to the network securely.
- 2364 12. After the device is connected and begins operating on the network, the Continuous  
2365 Authorization Service and the router make periodic asynchronous calls to each other that enable  
2366 the Continuous Authorization Service to monitor device behavior and constrain communications  
2367 to and from the device as needed in accordance with policy. In this manner, the Continuous  
2368 Authorization Service interacts with the router on an ongoing basis to verify that the device and  
2369 its operations continue to be authorized throughout the device's tenure on the network.
- 2370 This completes the network-layer onboarding process for Build 5 as well as the initialization of the Build  
2371 5 continuous authorization service. More details regarding the Build 5 implementation can be found at  
2372 <https://trustnetz.nqm.ai/docs/>.

## 2373 G.2.2 Build 5 Physical Architecture

2374 [Section 5.6](#) describes the physical architecture of Build 5.

## 2375 Appendix H Factory Provisioning Process

### 2376 H.1 Factory Provisioning Process

2377 The Factory Provisioning Process creates and provisions a private key into the device's secure storage;  
 2378 generates and signs the device's certificate (when BRSKI is supported), generates the device's DPP URI  
 2379 (when Wi-Fi Easy Connect is supported), or generates other bootstrapping information (when other  
 2380 trusted network-layer onboarding protocols are supported); provisions the device's certificate, DPP URI,  
 2381 or other bootstrapping information onto the device; and sends the device's certificate, DPP URI, or other  
 2382 bootstrapping information to the manufacturer's database, which will eventually make this information  
 2383 available to the device owner to use during network-layer onboarding.

#### 2384 H.1.1 Device Birth Credential Provisioning Methods

2385 There are various methods by which a device can be provisioned with its private key and bootstrapping  
 2386 information (e.g., its certificate, DPP URI, etc.) depending on how, where, and by what entity the  
 2387 public/private key pairs are generated [14]. Additional methods are also possible depending on how the  
 2388 device's certificate is provided to the manufacturer's database. The following are high-level descriptions  
 2389 of five potential methods for provisioning device birth credentials during various points in the device  
 2390 lifecycle. These methods are not intended to be exhaustive:

##### 2391 1. Method 1: Key Pair Generated on IoT Device

2392 Summary: Generate the private key on the device; device sends the device's bootstrapping  
 2393 information (e.g., the device's certificate or DPP URI) to the manufacturer's database. The steps for  
 2394 Method 1 are:

- 2395 a. The public/private key pair is generated on the device and stored in secure storage.
- 2396 b. The device generates and signs a CSR structure and sends the CSR to the  
 2397 manufacturer's IDevID CA, which sends a signed certificate (IDeVID) back to the device.
- 2398 c. If BRSKI is being supported, the device loads the certificate (IDeVID) into its secure  
 2399 storage; if Wi-Fi Easy Connect is being supported, the device creates a DPP URI and  
 2400 loads that into secure storage.
- 2401 d. The device sends the certificate or DPP URI to the manufacturer's database.

2402 One disadvantage of this method is that the device's random number generator is being relied  
 2403 upon to generate the key pair, and it is possible that a device's random number generator will not  
 2404 be as robust as the random number generator that would be included in an SE, for example. An  
 2405 advantage of this method is that the device's private key is not vulnerable to disclosure, assuming  
 2406 the device is equipped with a strong random number generator that is used for key generation and  
 2407 the private key is put into secure storage immediately upon generation.

##### 2408 2. Method 2: Key Pair Generated in Secure Element

2409 Summary: Generate the private key in a secure element on the device; IDevID CA provides the  
 2410 device certificate to the manufacturer's database. The steps for Method 2 are:

- 2411 a. The public/private key pair is generated within the device's SE.

- 2412            b. The device generates a CSR structure, the SE signs it, and the device sends the CSR to  
 2413            the manufacturer's IDevID CA, which sends a signed certificate (IDeVID) back to the  
 2414            device.  
 2415            c. If BRSKI is being supported, the device loads the certificate (IDeVID) into its secure  
 2416            storage; if Wi-Fi Easy Connect is being supported, the device creates a DPP URI and  
 2417            loads that into secure storage.  
 2418            d. The IDevID CA provides the certificate to the manufacturer's database. The  
 2419            manufacturer stores either the certificate (i.e., if BRSKI is being supported), or creates  
 2420            and stores a DPP URI (i.e., if Wi-Fi Easy Connect is being supported).

2421            Method 2 is similar to Method 1 except that in method 2, the key pair is generated and stored in a  
 2422            secure element and the manufacturer's database receives the signed certificate directly from the  
 2423            CA (either via a push or a pull) rather than via the device. An advantage of method 2 is that the  
 2424            device's private key is not vulnerable to disclosure because secure elements are normally equipped  
 2425            with a strong random number generator and tamper-proof storage.

### 2426            **3. Method 3: Key Pair Loaded into IoT Device**

2427            Summary: Generate the private key in the device factory and load it onto the device. The steps for  
 2428            Method 3 are:

- 2429            a. The public/private key pairs and certificates are generated in advance at the device  
 2430            factory and recorded in the manufacturer's database.  
 2431            b. The public/private key pair and certificate are loaded onto the device at the device  
 2432            factory.

2433            One advantage of this method is that there is no need to trust the random number generator on  
 2434            the device to generate strong public/private key pairs. However, the private keys may be  
 2435            vulnerable to disclosure during the period of time before they are provisioned into secure storage  
 2436            on the devices (and afterwards if they are not deleted once they have been copied into secure  
 2437            storage).

### 2438            **4. Method 4: Key Pair Pre-Provisioned onto Secure Element**

2439            Summary: Generate the private key in the SE and load the certificate on the device at the SE  
 2440            factory (SEF). The steps for Method 4 are:

- 2441            a. The public/private key pair and certificate are generated in advance in the SE at the  
 2442            SEF and the public key is recorded.  
 2443            b. The certificate is loaded onto the devices at the SEF.  
 2444            c. The certificates and the serial numbers of their corresponding devices are provided to  
 2445            the device manufacturer, and the device manufacturer can put them into the  
 2446            manufacturer database.  
 2447            d. The CA that signs the certificates that are generated and loaded onto the SEs may  
 2448            come from either the SEF or the device manufacturer. (Note: the CA is likely not  
 2449            located at the factory, which may be offshore.)

2450            Additional trust anchors can also be loaded into the SE at the SEF (e.g., code signing keys, server  
 2451            public keys for TLS connections, etc.) As with methods 2 and 3, one advantage of this method  
 2452            (method 4) is that there is no need to trust the random number generator on the device to  
 2453            generate strong public/private key pairs because the random number generator on the SE is used

2454 instead. With this method, the security level of the manufacturer’s factory does not need to be as  
2455 high as that of the SEF because all key generation and certificate signing is performed at the SEF;  
2456 the manufacturer can rely on the security of the SEF, which can be advantageous to the device  
2457 manufacturer, assuming that the SEF is in fact secure.

## 2458 **5. Method 5: Private Key Derived from Shared Seed**

2459 Summary: The device’s private key is derived from a shared seed. The steps for Method 5 are:

- 2460 a. The chip vendor embeds a random number into each IoT device (e.g., this may be  
2461 burned into fuses on the IoT device, inside the Trusted Execution Environment (TEE)).
- 2462 b. The IoT device manufacturer gets a copy of this seed securely (e.g., on a USB device  
2463 that is transported via trusted courier).
- 2464 c. On first boot, the IoT device generates a private key from this seed.
- 2465 d. The manufacturer uses the same seed to generate a public key and signs a certificate.

2466 As with method 4, with this option (method 5), there is no need for the IoT device manufacturer to have  
2467 a secure factory because the IoT device manufacturer may rely on the security of the chip manufacturer.  
2468 However, the IoT device manufacturer must also rely on the security of the courier or other mechanism  
2469 that is delivering the seed, and the IoT device manufacturer must ensure that the value of this seed is  
2470 not disclosed.

## 2471 **H.2 Factory Provisioning Builds – General Provisioning Process**

2472 The Factory Provisioning Builds implemented as part of this project simulate activities performed during  
2473 the IoT device manufacturing process to securely provision the device’s birth credentials (i.e., its private  
2474 key) into secure storage on the device and make the device’s network-layer bootstrapping information  
2475 available by enrolling the device’s public key into a database that will make this public key accessible to  
2476 the device owner in a form such as a certificate or DPP URI. The method used in the factory provisioning  
2477 builds most closely resembles *Method 2: Key Pair Generated on IoT Device*, as described in [Section H.1.1](#).

2478 There are several different potential versions of the factory provisioning build architecture depending  
2479 on whether the credentials being generated are designed to support BRSKI, Wi-Fi Easy Connect, Thread,  
2480 or some other trusted network-layer onboarding protocol. For example, when BRSKI is being supported,  
2481 the device bootstrapping information that is created takes the form of an 802.1AR certificate (IDevID); if  
2482 DPP is supported, it takes the form of a DPP URI.

2483 Because this project does not have access to a real factory or the tools necessary to provision birth  
2484 credentials directly into device firmware, the factory builds simulate the firmware loading process by  
2485 loading factory provisioning code into the IoT device (e.g., a Raspberry Pi device). This code plays the  
2486 role of the factory in the builds by instructing the SE that is attached to the IoT device to generate the  
2487 device’s private key and bootstrapping information. Once the IoT device has been provisioned with its  
2488 birth credentials in this manner, it can, in theory, be network-layer onboarded to one of the project  
2489 build networks.

### 2490 H.3 BRSKI Factory Provisioning Builds (NquiringMinds and SEALSQ)

2491 Two variants of the BRSKI Factory Provisioning Build were implemented:

- 2492     ▪ **NquiringMinds and SEALSQ implementation** (first version): SEALSQ, a subsidiary of WISEKey,  
2493     and NquiringMinds collaborated to implement one version of the BRSKI Factory Provisioning  
2494     Build. This build is designed to provision birth credentials to a Raspberry Pi device that has an  
2495     attached secure element provided by SEALSQ.
- 2496     ▪ **NquiringMinds and Infineon implementation** (second version): NquiringMinds implemented a  
2497     second version of the BRSKI Factory Provisioning Build using an Infineon SE. This build is  
2498     designed to provision birth credentials to a Raspberry Pi device that has an attached Infineon  
2499     Optiga SLB 9670 TPM 2.0.

#### 2500 H.3.1 BRSKI Factory Provisioning Build Technologies

2501 The general infrastructure for the first version of the BRSKI Factory Provisioning Build (i.e., the  
2502 NquiringMinds and SEALSQ implementation) is provided by SEALSQ. The first version of the BRSKI  
2503 Factory Provisioning Build infrastructure consists of:

- 2504     ▪ A SEALSQ VaultIC SE that is attached to the Raspberry Pi
- 2505     ▪ SEALSQ Factory Provisioning Code that is located on an SD card and that communicates with the  
2506     chip in the SE to
  - 2507         • create a P-256 Elliptic Curve public/private key pair within the SE,
  - 2508         • construct a certificate signing request, and
  - 2509         • store the certificate in the SE as well as send it to the manufacturer's database
- 2510     ▪ SEALSQ INeS CMS CA, a certificate authority for signing the device's birth certificate

2511 As mentioned earlier, separate factory provisioning builds are required for each network-layer  
2512 onboarding protocol being supported. A small amount of factory provisioning code is required to be  
2513 customized for each build, depending on the onboarding protocol that is supported and how the  
2514 bootstrapping information will be provided to the manufacturer. In this build, NquiringMinds provided  
2515 this code and made it available to the Raspberry Pi IoT device by placing it on an SD card. (This could be  
2516 either in a partition of the SD card that holds the device's BRSKI onboarding software or on a separate  
2517 SD card altogether).

2518 Table H-1 lists the technologies used in the first version of the BRSKI Factory Provisioning Build. It lists  
2519 the products used to instantiate each logical build component and the security function that the  
2520 component provides. The components listed are logical. They may be combined in physical form, e.g., a  
2521 single piece of hardware may both generate key pairs and provide secure storage.

2522 **Table H-1 First Version of the BRSKI Factory Provisioning Build Products and Technologies**

Component	Product	Function
Key Pair Generation Component	SEALSQ VaultIC and associated provisioning code	Generates and installs the public/private key pair into secure storage. The VaultIC has a SP800-90B certified random number generator for key pair generation.

Component	Product	Function
		<a href="#">[15]</a> <a href="#">[16]</a> <a href="#">[17]</a> Signs the certificate signing request that is sent to the CA.
Secure Storage	SEALSQ VaultIC	Storage on the IoT device that is designed to be protected from unauthorized access and capable of detecting attempts to hack or modify its contents. Used to generate, store, and process private keys, credentials, and other information that must be kept confidential.
General Factory Provisioning Instructions	SEALSQ Factory Provisioning Code	Creates a CSR associated with the key pair, installs the signed certificate into secure storage. Creates a record of devices that it has created and their certificates.
Build-specific Factory Provisioning Instructions	NquiringMinds Factory Provisioning Code	Sends device ownership information and the certificate received by the General Factory Provisioning code to the MASA.
Manufacturer Database	MASA	When devices are manufactured, device identity and bootstrapping information is stored here by the manufacturer. Eventually, this database makes the device's bootstrapping information available to the device owner. Device bootstrapping information is information that the device owner requires to perform trusted network-layer onboarding; for BRSKI, the bootstrapping information is a signed certificate that is sent to the MASA, along with information regarding the device's owner.
Certificate Authority (CA)	SEALSQ INeS CMS CA	Issues and signs certificates as needed.

2523 The second version of the BRSKI Factory Provisioning Build (i.e., the NquiringMinds implementation with  
2524 an Infineon SE) infrastructure consists of:

- 2525     ▪ An Infineon Optiga SLB 9670 TPM 2.0. that is attached to the Raspberry Pi
- 2526     ▪ Factory Provisioning Code written by NquiringMinds that is located on an SD card and that  
2527     communicates with the chip in SE to
  - 2528         • create a P-256 Elliptic Curve public/private key pair within the SE,
  - 2529         • construct a certificate signing request, and
  - 2530         • store the certificate in the SE as well as send it to the manufacturer's database
- 2531     ▪ NquiringMinds Manufacturer Provisioning Root (MPR) server, which signs the device's IDevID  
2532     birth certificate. It sits in the cloud and is securely contacted using the keys in the Infineon  
2533     Optiga secure element.

2534 In this build, NquiringMinds provided all of the factory provisioning code and made it available to the  
2535 Raspberry Pi IoT device by placing it on an SD card. (This could be either in a partition of the SD card that  
2536 holds the device's BRSKI onboarding software or on a separate SD card altogether).

2537 Table H-2 lists the technologies used in the second version of the BRSKI Factory Provisioning Build. It lists  
 2538 the products used to instantiate each logical build component and the security function that the  
 2539 component provides. The components listed are logical. They may be combined in physical form, e.g., a  
 2540 single piece of hardware may both generate key pairs and provide secure storage.

2541 **Table H-2 Second Version of the BRSKI Factory Provisioning Build Products and Technologies**

Component	Product	Function
Key Pair Generation Component	Infineon TPM and associated provisioning code	Generates and installs the public/private key pair into secure storage. Signs the certificate signing request that is sent to the CA.
Secure Storage	Infineon TPM	Storage on the IoT device that is designed to be protected from unauthorized access and capable of detecting attempts to hack or modify its contents. Used to generate, store, and process private keys, credentials, and other information that must be kept confidential.
General Factory Provisioning Instructions	Infineon TPM-specific Factory Provisioning Code	Creates a CSR associated with the key pair, installs the signed certificate into secure storage. Creates a record of devices that it has created and their certificates.
Build-specific Factory Provisioning Instructions	Build-specific Factory Provisioning Code	Sends device ownership information and the signed certificate to the MASA.
Manufacturer Database	MASA	When devices are manufactured, device identity and bootstrapping information is stored here by the manufacturer. Eventually, this database makes the device's bootstrapping information available to the device owner. Device bootstrapping information is information that the device owner requires to perform trusted network-layer onboarding; for BRSKI, the bootstrapping information is a signed certificate that is sent to the MASA, along with information regarding the device's owner.
Certificate Authority (CA)	SEALSQ INeS CMS CA NquiringMinds On-premises CA	Issues and signs certificates as needed.

### 2542 H.3.2 BRSKI Factory Provisioning Build Logical Architectures

2543 [Figure H-1](#) depicts the logical architecture of the first version of the BRSKI factory provisioning build (i.e.,  
 2544 the NquiringMinds and SEALSQ implementation) and is annotated with the steps that are performed in  
 2545 this build to prepare IoT devices for network-layer onboarding using the BRSKI protocol. [Figure H-1](#)  
 2546 shows a Raspberry Pi device with a SEALSQ VaultIC SE attached. An SD card that contains factory  
 2547 provisioning code provided by SEALSQ and NquiringMinds is also required. To perform factory

2548 provisioning using this build, insert the SD card into the Raspberry Pi, as depicted (or activate the code in  
2549 the factory provisioning partition of the SD card that is already in the Raspberry Pi). The SEALSQ  
2550 software will boot up and perform the following steps to simulate the activities of a factory:

- 2551 1. Instruct the SE to generate and store a private/public key pair
- 2552 2. Create a certificate signing request for this key pair and have the SE sign it
- 2553 3. Send the signed CSR to the IDevID CA (i.e., to the INeS CA that is operated by SEALSQ)
- 2554 4. Receive back the signed certificate from the CA
- 2555 5. Load the certificate into the SE
- 2556 6. Send the certificate (along with device ownership information) to the manufacturer's database,  
2557 which in this case is the MASA that is trusted by the owner

2558 This completes the steps performed as part of the first version of the BRSKI Factory Provisioning Build.  
2559 Once complete, shipment of the device to its owner can be simulated by walking the device across the  
2560 room in the NCCoE laboratory to the Build 5 (NquiringMinds) implementation and replacing the SD card  
2561 that has the factory provisioning code on it with an SD card that has the BRSKI onboarding code on it.  
2562 (Alternatively, if the factory provisioning code and the BRSKI onboarding code are stored in separate  
2563 partitions of the same SD card, shipment of the device to its owner can be simulated by booting up the  
2564 code in the onboarding partition.) Build 5 is designed to execute this BRSKI onboarding software, which  
2565 onboards the device to the device owner's network by provisioning the device with an LDevID that will  
2566 serve as its network-layer credential. Such successful network-layer onboarding of the newly  
2567 provisioned device using the BRSKI protocol by Build 5 would serve to confirm that the first version of  
2568 the BRSKI factory provisioning process successfully provisioned the device with its birth credentials. At  
2569 the time of this writing, however, this confirmation process was not able to be performed. In order to  
2570 securely network-layer onboard the newly provisioned Raspberry Pi using the BRSKI protocol, the  
2571 Raspberry Pi's onboarding software would need to be written to use the private key stored in the  
2572 SEALSQ secure element when running the BRSKI protocol. Such software was not yet available at the  
2573 time of this publication. The BRSKI onboarding code on the Raspberry Pi does not currently use the  
2574 private key stored in the SEALSQ SE. As a result, Build 5 was not able to onboard this factory Pi as a way  
2575 of confirming that the first version of the BRSKI factory build process completed successfully. The  
2576 repository that hosts the code for this implementation can be found here at the [trustnetz-se Github](#)  
2577 [repository](#).

2578 Figure H-1 Logical Architecture of the First Version of the BRSKI Factory Provisioning Build

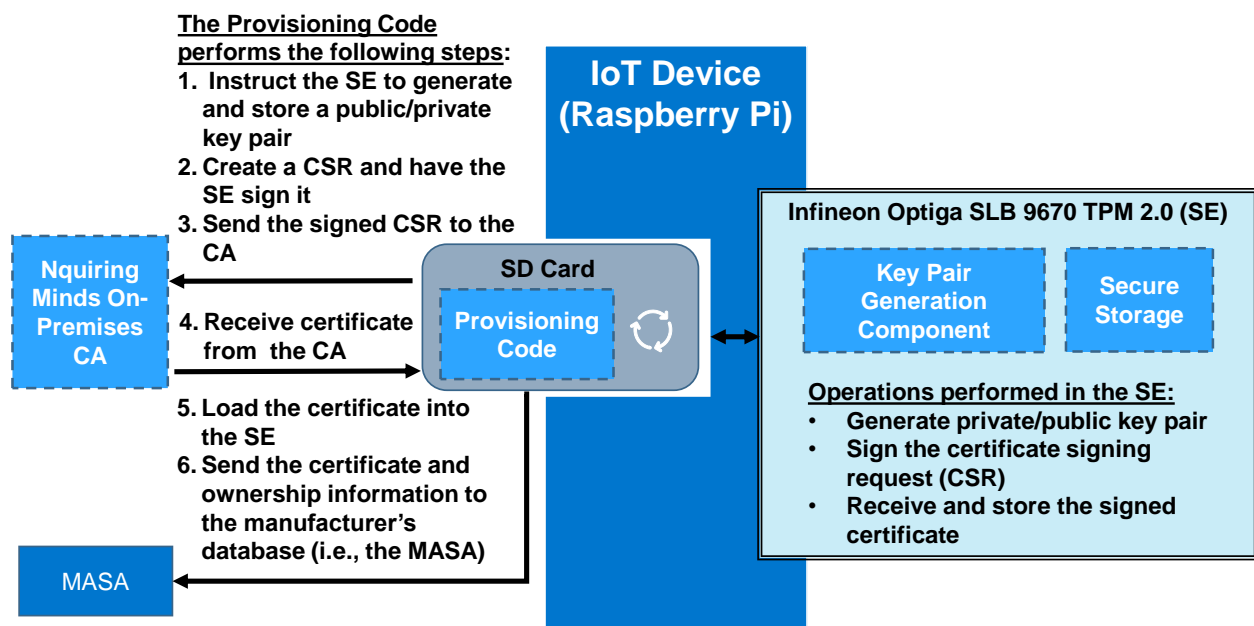

2579 [Figure H-2](#) depicts the logical architecture of the second version of the BRSKI factory provisioning build  
 2580 and is annotated with the steps that are performed in this build to prepare IoT devices for network-layer  
 2581 onboarding using the BRSKI protocol. Figure H-2 shows a Raspberry Pi device with an Infineon Optiga  
 2582 SLB 9670 TPM 2.0 SE attached. An SD card that contains factory provisioning code provided by  
 2583 NquiringMinds is also required. To perform factory provisioning using this build, insert the SD card into  
 2584 the Raspberry Pi, as depicted (or activate the code in the factory provisioning partition of the SD card  
 2585 that is already in the Raspberry Pi). The factory provisioning code software will boot up and perform the  
 2586 following steps to simulate the activities of a factory:

- 2587 1. Instruct the Infineon SE to generate and store a private/public key pair
- 2588 2. Create a certificate signing request for this key pair and have the SE sign it
- 2589 3. Send the signed CSR to the IDevID CA (i.e., to the NquiringMinds on-premises CA/Manufacturer  
 2590 Provisioning Root)
- 2591 4. Receive back the signed certificate from the CA
- 2592 5. Load the certificate into the SE
- 2593 6. Send the certificate (along with device ownership information) to the manufacturer's database,  
 2594 which in this case is the MASA that is trusted by the owner

2595 This completes the steps performed as part of the second version of the BRSKI Factory Provisioning  
 2596 Build. Once complete, shipment of the device to its owner can be simulated by walking the device across  
 2597 the room in the NCCoE laboratory to the Build 5 (NquiringMinds) implementation and replacing the SD  
 2598 card that has the factory provisioning code on it with an SD card that has the BRSKI onboarding code  
 2599 on it. (Alternatively, if the factory provisioning code and the BRSKI onboarding code are stored in  
 2600 separate partitions of the same SD card, shipment of the device to its owner can be simulated by

2601 booting up the code in the onboarding partition.) Build 5 executes a modification of the BRSKI  
 2602 onboarding software that has been modified to use the IDevID resident on the Infineon TPM throughout  
 2603 the protocol flow, ensuring the device’s IDevID’s private key is never made public and never leaves the  
 2604 secure element. Specifically, the critical signing operations and the TLS negotiation steps are fully  
 2605 secured by the SE. The full BRSKI onboarding flow provisions a new LDevID onto the device. This LDevID  
 2606 provides the secure method for the device to connect to the domain owner’s network. This successful  
 2607 network-layer onboarding of the IoT device by Build 5 serves as confirmation that the second version of  
 2608 the BRSKI factory provisioning process successfully provisioned the device with its birth credentials.

2609 **Figure H-2 Logical Architecture of the Second Version of the BRSKI Factory Provisioning Build**

2610 **H.3.3 BRSKI Factory Provisioning Build Physical Architectures**

2611 [Section 5.6.1](#) describes the physical architecture of the BRSKI Factory Provisioning Builds.

2612 **H.4 Wi-Fi Easy Connect Factory Provisioning Build (SEALSQ and**  
 2613 **Aruba/HPE)**

2614 SEALSQ, a subsidiary of WISEKey, and Aruba/HPE implemented a Wi-Fi Easy Connect Factory  
 2615 Provisioning Build. This build is designed to provision birth credentials to a Raspberry Pi device that has  
 2616 an attached secure element provided by SEALSQ.

2617 **H.4.1 Wi-Fi Easy Connect Factory Provisioning Build Technologies**

2618 The general infrastructure for the Wi-Fi Easy Connect Factory Provisioning Build is provided by SEALSQ.  
 2619 The Wi-Fi Easy Connect Factory Provisioning Build infrastructure consists of:

- 2620 ■ A SEALSQ VaultIC SE that is attached to the Raspberry Pi

- 2621       ▪ SEALSQ Factory Provisioning Code that is located on an SD card and that communicates with the  
2622       chip in the SE to:
- 2623           • create a P-256 Elliptic Curve public/private key pair within the SE,
  - 2624           • use the public key to construct a DPP URI
  - 2625           • export the DPP URI and convert it into a QR code

2626 Table H-3 lists the technologies used in the Wi-Fi Easy Connect Factory Provisioning Build. It lists the  
2627 products used to instantiate each logical build component and the security function that the component  
2628 provides. The components listed are logical. They may be combined in physical form, e.g., a single piece  
2629 of hardware may both generate key pairs and provide secure storage.

2630 **Table H-3 Wi-Fi Easy Connect Factory Provisioning Build Products and Technologies**

Component	Product	Function
Key Pair Generation Component	SEALSQ VaultIC and associated provisioning code	Generates and installs the public/private key pair into secure storage. The VaultIC has a SP800-90B certified random number generator for key pair generation. [17]
Secure Storage	SEALSQ VaultIC	Storage on the IoT device that is designed to be protected from unauthorized access and capable of detecting attempts to hack or modify its contents. Used to generate, store, and process private keys, credentials, and other information that must be kept confidential.
General Factory Provisioning Instructions	SEALSQ Factory Provisioning Code	Creates a public/private key pair.
Build-specific Factory Provisioning Instructions	Aruba/HPE Factory Provisioning Code	Uses the public key to create a DPP URI. Exports the DPP URI and converts it into a QR code.
Manufacturer Database	Manufacturer cloud or imprint on device	The DPP URI information is stored in the QR code and is the mechanism for conveying the device's bootstrapping information to the device owner.

#### 2631 H.4.2 Wi-Fi Easy Connect Factory Provisioning Build Logical Architecture

2632 [Figure H-3](#) depicts the logical architecture of the Wi-Fi Easy Connect factory provisioning build and is  
2633 annotated with the steps that are performed in this build to prepare Raspberry Pi IoT devices for  
2634 network-layer onboarding using the Wi-Fi Easy Connect protocol. Figure H-3 shows a Raspberry Pi device  
2635 with a SEALSQ VaultIC SE attached. Factory provisioning code provided by SEALSQ and Aruba/HPE must  
2636 also be loaded. In Figure H-3, this code is shown as being on an SD card. The factory provisioning  
2637 software will boot up and perform the following steps to simulate the activities of a factory:

- 2638       1. Instruct the SE to generate and store a private/public key pair
- 2639       2. Use the public key to create a DPP URI

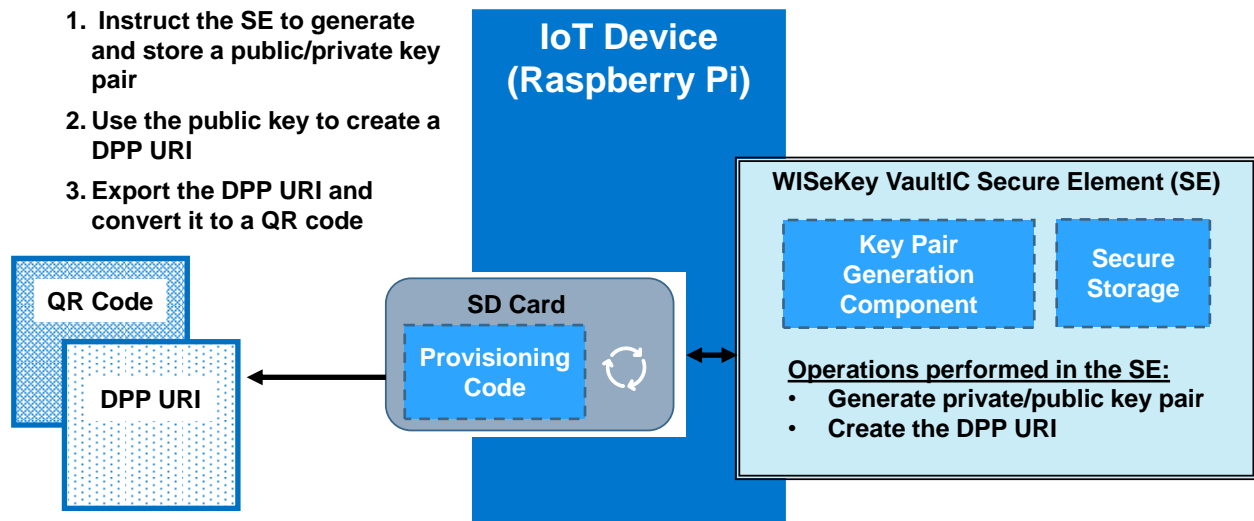

2640 3. Export the DPP URI and convert it into a QR code

2641 This completes the steps performed as part of the Wi-Fi Easy Connect Factory Provisioning Build. Once  
 2642 complete, shipment of the device to its owner can be simulated by walking the device across the room  
 2643 in the NCCoE laboratory to the Build 1 (Aruba/HPE) implementation. Build 1 uses the Wi-Fi Easy Connect  
 2644 protocol to network-layer onboard the device to the device owner’s network by provisioning the device  
 2645 with connector that will serve as its network-layer credential. Successful network-layer onboarding of  
 2646 the newly provisioned device using the Wi-Fi Easy Connect protocol by Build 1 would serve to confirm  
 2647 that the Wi-Fi Easy Connect factory provisioning process correctly provisioned the device with its birth  
 2648 credentials. At the time of this writing, however, this confirmation process was not able to be  
 2649 performed. In order to securely network-layer onboard the newly provisioned Raspberry Pi using the  
 2650 Wi-Fi Easy Connect protocol, the Raspberry Pi would need to be equipped with a firmware image that  
 2651 uses the private key stored in the secure element when running the Wi-Fi Easy Connect protocol. Such  
 2652 firmware was not yet available at the time of this publication. The Wi-Fi Easy Connect code on the  
 2653 Raspberry Pi does not use the private key stored in the SE at this time. Confirmation that the factory  
 2654 build process completed successfully is limited to inspection of the .PNG file and .URI file that were  
 2655 created to display the QR Code and the device’s DPP URI, respectively.

2656 **Figure H-3 Logical Architecture of the Wi-Fi Easy Connect Factory Provisioning Build**

**The Provisioning Code performs the following steps:**

1. Instruct the SE to generate and store a public/private key pair
2. Use the public key to create a DPP URI
3. Export the DPP URI and convert it to a QR code

2657 **H.4.3 Wi-Fi Easy Connect Factory Provisioning Build Physical Architecture**

2658 [Section 5.2.1](#) describes the physical architecture of the Factory Provisioning Build.
